Title
Diamond Semiotic Short Studies: A Collection of papers on semiotics

Archive-Number / Categories
2_41 / K04, K05, K06, K08, K02

Publication Date
2009

Keywords
Diamond Theory, Semiotics, Category Theory, Polycontexturaity

Disciplines
Cybernetics, Artificial Intelligence and Robotics, Logic and Foundations of Mathematics, Social and Behavioral Sciences, Life Sciences, Theory of Science, Philosophy of Science

Abstract
A collection of papers on semiotics, polycontexturality and diamond theory

Citation Information / How to cite

NOTE
1. The original collection of texts has been extended by two texts, namely "Generalized Diamonds" and "Diamond Disremption".
2. All texts of this collection can also be found individually in www.vordenker.de. The URL is next to the title in the table of contents under the [#] symbol.

# Diamond Semiotic Short Studies

A collection of papers on semiotics, polycontexturality and diamond theory

## Table of Contents

(compiled by EvGo, April 2017)

### Generalized Diamonds:

- From monosemic to tectonic complementarity
  1. Generalized Diamond Conditions
     1.1. Architectonics of diamonds
     1.2. Polysemic complementarity
     1.3. Tectonic metamorphosis

### Diamond Disremption:

- Diamond interpretation of the kenomic succession operation
  1. Diamondization of kenogrammatics
     1.1. Descriptive interpretation of disremption
     1.2. Semiotic Concatenation
     1.3. Kenomic Disremption
     1.4. Diamond modeling of hermeneutics
     1.5. Diamond explication of natural numbers
     1.6. Initial and final objects in diamonds
  2. Kenomic sameness
     2.1. Semiotic identity
     2.2. Monomorphic equivalence
     2.3. Chiastic sameness
     2.4. Diamond strangeness

### Diamond Semiotics:

- An interplay of semiotic and graphematic diamonds
  1. Mathematical semiotics and diamonds
     1.1. Semiotics, again?
     1.2. Toth’s semiotic diamonds
     1.3. General micro-structure of semiotic diamonds
     1.4. Compositions of semiotic diamonds
     1.5. Semiotic operations
  2. General macro-structure of semiotic diamonds
     2.1. Dyads and triads (n-är vs. n-adisch)
     2.2. Semiotic operations
     2.3. Semiotic monadic sign compositions
     2.4. Diamond monadic sign compositions
     2.5. Dyadic sign compositions
     2.6. Local-global-heteromorphisms
     2.7. Composition of semiotic diamonds
  3. Goguen’s semiotics: From Peirce to Pierce
  4. Notes and References

---

The original collection of texts has been extended by two texts, namely "Generalized Diamonds" and "Diamond Disremption". All texts of this collection can also be found individually in www.vordenker.de. The URL is next to the title in the table of contents under the [#] symbol.
Toth’s semiotic diamonds:  
Analyzing construction principles for semiotic diamonds
Sketch of Toth’s semiotics
Response to Toth’s remark
Toth’s general procedure
Playing the game

Sketch on semiotics in diamonds:  
Embedding semiotics into anchored diamonds
Abstract
1. Diamond embedments of semiotics
   1.1. Semiotics within semiotics
   1.2. Diamond semiotic values
   1.3. Diamond semiotic interpretations of (M, O,I)
2. Anchored diamonds
   2.1. Anchored semiotics
   2.2. Anchored diamonds
   2.3. Dissemination of diamonds
Notes

Triadic Diamonds:  
Robertson’s algebra of triadic relations, Gunther’s founding relations and diamond triads
1. Beyond binary relations?
   1.1. Triads, trilogs, triplets
   1.2. Morphisms as triads
2. Diamond triads
   2.1. Robertson’s Trilog
   2.2. Triadic diamonds
   2.3. Founded triads modeled by triadic diamonds
3. Günther’s founding relation
3.1. The idea of founding relations

Diamond Relations:  
Sketch of a theory of diamond relations
1. Diamond relations
   1.1. Set-theoretical relations
   1.2. Diamond theory of relations
2. Category PATH
   2.1. Motivation
   2.2. Formal description
3. Diamond of JOURNs
   3.1. The journey map metaphor
   3.2. Formal description of JOURN
4. Diamond set theory
5. Architectonics of disseminated categories
   5.1. Rhizomatics
   5.2. Dissemination between lines, stars, circles and flags

Elements of Diamond Set Theory:  
Some more parts of the mosaic towards semiotics, logic, arithmetic and category theory
Abstract
1. Diamond set theory
   1.1. Sets, universes, conglomerations
   1.2. Diamond strategies for bi-objects
   1.3. Elements of a diamond theory of conglomerates
2. Quantification in polycontextural logics
   2.1. Tableau rules for polycontextual quantifiers
   2.2. Polylogical quantification rules
   2.3. Quantification for diamond theory
   2.4. Smullyan unification for diamond quantification
3. Interplay of semiotics, logics, set theory and arithmetic
   3.1. Strategy
   3.2. Sketch
Interactional operators in diamond semiotics: From polylogical transjunctions to polysemiotic interactions and reflections

1. Semiotics and polylogics
   1.1. Motivation
   1.2. Is there a privileged number for dissemination?

2. Dissemination of semiotics
   2.1. Contextural decomposition triadic systems
   2.2. Semiotic decomposition of tetradic systems
   2.3. Interplay of semiotics, logics and arithmetic
   2.4. Multi-dimensional and polycontextural semiotics

3. Interactivity in poly-semiotics
   3.1. Interactions between (2,2)-subsystems of \( \text{Sem}^{(3,2)} \)
   3.2. Interactions between (3, 3)-subsystems of \( \text{Sem}^{(4,2,3)} \)
   3.3. Interaction and reflectionality

4. Logification of semiotics

5. Interactions in diamonds
   5.1. Interactions in diamonds
   5.2. Interactions between diamonds

2. From signs to textemes
   2.1. Again then, what is a polycontextural sign?
Generalized Diamonds

From monosemic to tectonic complementarity

Rudolf Kaehr Dr.
ThinkArt Lab Glasgow

Abstract
The construction of diamonds can be generalized towards polysemic and metamorphic interactions between categories and saltatories.

1. Generalized Diamond Conditions

1.1. Architectonics of diamonds
Composition in diamonds can be generalized towards polysemic and metamorphic interactions between categories and saltatories.

After having developed some insights and experiences with the diamond approach and its complementary structures, a design of diamond category theory might be introduced which is not as close to the introductory analogy to classic category theory. Following the classic strategy of academic research a generalization of the introduced concepts of diamond category theory shall be sketched.

To some degree, such generalizations are obvious, but nevertheless quiet intriguing albeit a tedious pleasure.

Asymmetry in the interplay
The first introduction of the diamond category concept is based on the strict and primary distinction of categorical objects and morphisms and their composition. A saltatorical hetero-morphism is thus an abstraction from the composition operation on morphisms resulting in an asymmetry between categories and saltatories. A composition is defined on 2 morphism, an abstraction on the composition is establishing a single hetero-morphism as a reflection of the categorical composition activity in a saltatory. Hence, a commutative composition of 2 morphism is mirrored by only one hetero-morphism. Thus, the commutativity of the composition of 2 morphism has no direct proper correspondence in the commutativity of a single heteromorphism.

Therefore, the general sentence “To each commutativity in a category a commutativity in a saltatory corresponds” leads to conflicts if we use the strict and restricted introduction of diamonds.

\[\text{Diamond Commutativity} \quad \begin{cases} (g \circ f) = (g \circ f) \circ i \\
\text{with} \quad \text{cc}(f) = \text{dom}(g) \\
\text{and} \quad \omega(f) \downarrow \alpha(g) \end{cases} \]

\[\text{ saltatory} \]

\[\begin{array}{c}
\text{A} \xrightarrow{f} \text{B} \\
\text{h} \searrow \text{g} \\
\text{C} \xleftarrow{a \leftrightarrow b}
\end{array}\]

\[\text{category}\]

**Balancing the interplay**

A. Complementarity of features (properties, structures, data):
1. in parallel, commutativity to commutativity
2. mixed, say commutativity to associativity

B. Bridging features of complementarity

All those combinations are possible with a liberalization in the definition of the constitutive rules for diamonds.

That is, the complementarity of a categorical composition has not to be represented in a single elementary hetero-morphism it could be mapped into a complexion of hetero-morphisms.

With that, a free, but still reasonable mixture of features could be realized.

**Architectonics**

\[ \begin{align*}
\text{id} & \quad \text{id} \\
\omega_1 & \quad \text{morphism } f \\
\omega_2 & \quad \omega_2 \\
\omega_3 & \quad \text{morphism } g \\
\omega_4 & \quad \text{hetero-functor}
\end{align*} \]

This example could be read as a complementary distribution of a categorical composition of morphisms, hence a category, and a saltatorial functorial mapping of saltatories. Hence, the difference operation is not reduced to polysemy but is a mapping between morphisms of a category and functors in a saltatory. Such a mapping is crossing tectonic levels, here, between morphisms and functors.

Functors are mappings between categories, thus, in our case, they are *hetero-functors* as mappings between saltatories. Functors in categories are associative under composition, in saltatories they are associative under saltisition. That is, the jump-operation holds not only for hetero-morphisms but for hetero-functors too.

For alone standing categories it seems not to make any sense to mix morphisms with functors in one design. For diamonds, the possibility to mix types between categories and saltatories is opening up a new kind of flexibility in modeling complex systems.

**Standard diamond definitions**
Identity is a mapping onto-itself as itself.

For each object X of a category an identity morphism, ID \([X, X]\), which has domain X in the category and codomain X in the same category exists. Called ID \(X\) or id \(X\) for ID \([X, X]\).

For each object x of a saltatory an identity morphism, ID \([x, x]\), which has domain x in the saltatory and codomain x in the same saltatory exists. Called ID \(x\) or id \(x\) for ID \([x, x]\).

Difference is a mapping onto-itself as other.

For each object X of a category a difference morphism, DIFF \([X, X]\), which has domain X in the category and codomain x in the saltatory exists. For each object x of a saltatory a difference morphism, DIFF \([x, x]\), which has domain x in the saltatory and codomain X in the category exists.

For each cat-object X an identity ID \(X\) in Cat(X, X). For each salt-object x an identity ID \(x\) in Salt(x, x) exists. And, for each bi-object [X, x] a difference DIFF \([X, x]\) between Salt(x, x) and Cat(X, X).

**Tectonics of Diamonds**

According to the presentation of categories by Eugenia Chang, a category consists of Data, Structure and Properties (DSP). Categories as graphs with structure are defined as DSP in the following sense:

1. **Definition**: A **category** is given by
   1. **Data**: a diagram \(C_1 \xrightarrow{s} C_0\) in Set
   2. **Structure**: composition and identities
   3. **Properties**: unit and associativity

A first step in developing a tectonics for diamonds is introduced by an inversion of the full DSP-scheme (Data, Structure, Properties) from DSP to PSD. That is, the properties are determining the choice for the structure and data of the structuration.

A second step is diamondizing PSD.
- Diamonds are conceived as an interplay of categories and saltatories, hence PSD has to be distributed and involved into a complementary and chiastic interplay, resulting in: YPSD.
- Disseminated Diamonds, YPSD, are involved into interactionality and reflectionality as iterative and accretive interactions, resulting in IYPSD.
- Interacting YDSPs are localized and positioned into the kenomic grid by the place-designator, resulting in LIYPSD.

Hence the diamondized DSP results into the LIY(PSD)- architecture.

**DSPYIL-Architectonics of diamonds**

i) **Data**: 2-diagram \(C_1 \xrightarrow{s,t} C_0 \xleftarrow{\text{diff}} C_1\) in 2-Set,

ii) **Structure**: composition, identities + saltistition, difference,
iii) **Properties**: unit, associativity + diversity, jump law,

iv) **Interplay**: complementarity and chiasm between category and saltatory,

(v) **Interactions**: diamonds with diamonds, iterative/accretive,

vi) **Localisation**: kenomic grid, place-designator.

A third step is freely interchanging the structure and property features of categories and saltatories in the sense of metamorphic transformations realized by the super-operators.

Free mixtures of structures (commutativity of composition and identities) with properties (unit, associativity) and its saltatorical equivalents (saltisition, difference) shall be introduced.

\[
\text{Interplay } [\text{Diam}] = \chi([\text{Cat, Salt}], \{ D, S, P \})
\]

\[
\chi([\text{Cat, Salt}], \{ D, S, P \}) = \begin{pmatrix}
DD & DS & DP \\
SD & SS & SP \\
PD & PS & PP \\
\end{pmatrix},
\]

with \( [XY] = \text{Cat}(X) \rightarrow \text{Salt}(Y), X, Y \in \{ D, S, P \} \).

\text{num } [D, S, P] = 3, \text{ num } [X \{ D, S, P \}] = 3 \times 3 = 9

### 1.2. Polysemic complementarity

Up to now, a standard interpretation was leading the construction of diamond category theory. That is, the range of the difference relation as part of the definition of the bi-object of diamonds placed between categories and saltatories had to be monosemic and preserving the tectonics of the categories, i.e. objects to objects and morphisms to morphisms. That is, between a categorical object \( X \) and a saltatorical object \( x \), a 1-1-mapping was supposed.

**Polysemic-Mappings:**

<table>
<thead>
<tr>
<th>one-to-one</th>
<th>one-to-many</th>
<th>many-to-one</th>
<th>many-to-many</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \text{bi-Object } [X, x] )</td>
<td>( \text{bi-Object } [X, x^{(n)}] )</td>
<td>( \text{bi-Object } [X^{(n)}, x] )</td>
<td>( \text{bi-Object } [X^{(n)}, x^{(m)}] )</td>
</tr>
<tr>
<td>( \text{id} )</td>
<td>( \chi^{(m)} \in \text{Salt} )</td>
<td>( \chi^{(n)} \in \text{Cat} )</td>
<td>( \chi^{(n)} \in \text{Salt} )</td>
</tr>
<tr>
<td>( x \in \text{Salt} )</td>
<td>( x^{(m)} \in \text{Cat} )</td>
<td>( \chi^{(n)} \in \text{Cat} )</td>
<td>( x^{(m)} \in \text{Salt} )</td>
</tr>
<tr>
<td>( \chi \in \text{Cat} )</td>
<td>( \chi^{(m)} \in \text{Cat} )</td>
<td>( \chi^{(m)} \in \text{Cat} )</td>
<td>( \chi^{(n)} \in \text{Salt} )</td>
</tr>
</tbody>
</table>

This decision for a mono-semic approach is guaranteeing the diamonds a strong stability. But it also can be regarded as a restriction. Hence, a polysemic and trans-tectonic approach shall be introduced.

Polysemic relations in regard of the basic terms of identity and difference shall be sketched.

**Protological comment**

From a proto-theoretical point of view, some comments about the status of the difference relation would be appropriate. The usual problem of use and mention of terms, here "relation", in a case of abuse of terms, is demanding for justification. If the concept of relation is entirely covered by categories and the difference between categories and saltatories is alien to categories, how has the concept of a relationship between categories and saltatories be deconstructed to model both, its status as a proper relation and as concept of relationship beyond its proper definition of relation? This question remains in the to-do box.

### 1.3. Tectonic metamorphosis

Minimal tectonics for categories is given by the 3-tuple (morphisms, functors, natural transformations).
Tectonic inter-relations between categories and saltatorys:
From composition of morphisms to a mirroring in hetero-morphisms,
From composition of morphisms to a mirroring in hetero-functors,
From composition of functors to a mirroring in saltatorial natural transformations.

Metamorphism was introduced in ConTeXtures as a chiastic interplay between topics (types) of programming and contextures.

**General scheme for tectonic metamorphosis:**

\[ \text{Type} - \text{Chiasm} \]

\[ \text{Chiasm}(\text{Diam}) = \chi(\text{Cat}, \text{Salt}, \text{type}_{\text{Cat}}, \text{type}_{\text{Salt}}) , \text{type} = \{\text{object}, \text{morphism, functor, natural transformation}\} \]

\[
\begin{array}{ccc}
\text{bi} - \text{Object} & \text{bi} - \text{Object} & \text{bi} - \text{Object} \\
\text{X, Salt} & \text{Cat, x} & \text{Cat, Salt} \\
\begin{array}{c}
\tilde{\text{id}} \\
\text{Salt} e \text{Salt} \\
\text{diff}(\text{X-Salt}) \\
\text{X} e \text{Cat} \\
\tilde{\text{id}}
\end{array} & \\
\begin{array}{c}
\tilde{\text{id}} \\
\text{x} e \text{Salt} \\
\text{diff}(\text{Cat-x}) \\
\text{Cat} e \text{Cat} \\
\tilde{\text{id}}
\end{array} & \\
\begin{array}{c}
\tilde{\text{id}} \\
\text{Salt} e \text{Salt} \\
\text{diff}(\text{Cat-Salt}) \\
\text{Cat} e \text{Cat} \\
\tilde{\text{id}}
\end{array}
\end{array}
\]

Metamorphic chiasms between categories and saltatories in diamonds are supported by the generalized difference operation between categories and saltatories.

**Polytopic Chiasms in ConTeXtures**

Polytopics, as a distribution of different topics over different contextures, in a reflectional and/or interactional mode, had been first introduced by the new paradigm of contextural programming, ConTeXtures. This introduction is restricted to polycontextural constellations only. The diamond approach to contextural programming wasn't yet at hand.

The following example shows a distribution of the topics num, list and Boolean over 3 mediated reflectional contextures of the polycontextural matrix.

\[ \text{samba}^{\Phi}(\text{repl, } \Theta, \Theta) - \text{horizon} \]

\[
\begin{array}{c}
\text{thematize}(\text{zero, nil, false}) \\
\text{identify contexture}_{1,1} \\
\text{define zero} \\
\text{lambda } (f) \\
\text{lambda } (x) \\
\text{define contexture}_{1,2} \\
\text{define zero}_{1,1} \text{ as nil} \\
\text{lambda } (i) \\
\text{true} \\
\text{define contexture}_{1,3} \\
\text{define nil}_{2,2} \text{ as false} \\
\text{lambda } (i e b) \\
b
\end{array}
\]

\[ \begin{array}{c}
\tilde{\phi}_{2,1} \quad \tilde{\phi}_{3,1} \\
\tilde{\phi}_{2,2} \quad \tilde{\phi}_{3,2} \\
\tilde{\phi}_{2,3} \quad \tilde{\phi}_{3,3}
\end{array} \]

ConTeXtures are dealing with types as topics, mono- and poly-topics of complex constellations of programming languages.

This reflectional metamorphic transformation example shows a polytopic situation with the topics Number,
List and Boolean.

Thus, "define name" is an abbreviation of "define name, as name, i.e. name_i = name_j"; which is an application of the as-abstraction.

- replication repl, in this example, is a metamorphic replication and is not replicating isolated configurations.

Exchange relations:

- "define zero" is "define zero as zero", as the start of the electoral levels. It could itself be produced by a predecessor level,
- define zero in contexture1.1 as zero in contexture1.1
- "define nil" is "define zero as nil",
  as: define zero from contexture1.1 as nil in contexture1.2
- "define false" is "define nil as false",
  as: define nil from contexture1.2 as false in contexture1.3.

Obviously, transcontextual type transformations are not identical with intra-contextual type derivations in the sense of the lambda calculus. The first are crossing the borders of contextures, from types in one contextures to other types in other contextures. This can happen successively, from one contexture to another contexture, or simultaneously, from a multitude of types in one or more contextures to a multitude of different types of different contextures. The lambda derivations are monochonctural in all their derivational transformations, and are not leaving their contextures, i.e. the borders of the formal system.

Diamond Chiasm Scheme

Diamond Chiasm - Scheme

\[
\chi[\text{Cat, Salt, } M, \sigma] = \begin{cases} 
\text{level}_{\text{Cat}} : [M \to \sigma] \\
\text{level}_{\text{Salt}} : [\sigma \to M]
\end{cases}
\]

Type - Term - Chiasm

\[
\text{Dia}_n^{[2,1]} = \chi[\text{Cat, Salt, } M, \sigma] = \begin{cases} 
[M \to \sigma]_{\text{Cat}} \downarrow [M \to \sigma]_{\text{Salt}} \\
[M_{\text{Cat}} \equiv M_{\text{Salt}}], [\sigma_{\text{Cat}} \equiv \sigma_{\text{Salt}}]
\end{cases}
\]
Catalogue of structurations

Categories: \( [1, 3, 1] = (1 \text{ category}, 3 \text{ morphism}, 1 \text{ composition (fulfilling the matching conditions)}) \).

\[
\text{level}_{\text{Cat}} : \left[ \begin{array}{c}
M \rightarrow \sigma \\
\end{array} \right] \times \left[ \begin{array}{c}
M \rightarrow \sigma \\
\end{array} \right] \times \cdots \times \left[ \begin{array}{c}
M \rightarrow \sigma \\
\end{array} \right]^{(n)} \quad \text{iteration (n)}
\]

Chiasm: \( [1, 2, 2, 2] = (1 \text{ chiasm}, 2 \text{ order}, 2 \text{ exchange and 2 coincidence relations}) \).

\[
\text{Chiasm}^{(2,1)} = \chi \left[ \text{Cat, Salt, } M, \sigma \right]
\]

\[
\begin{bmatrix}
\text{level}_{\text{Cat}} : \left[ \begin{array}{c}
M \rightarrow \sigma \\
\end{array} \right] \\
\text{level}_{\text{Salt}} : \left[ \begin{array}{c}
\sigma \leftarrow M \\
\end{array} \right]
\end{bmatrix}
\]

Polycontextural mediation: \( [1, 2, 3, 4] = (1 \text{ mediation}, 2 \text{ exchange}, 3 \text{ order}, 4 \text{ coincidence relations}) \).

\[
\text{Poly}^{(2,1)} = \chi \left[ \text{Cat, Salt, } M, \sigma \right]
\]

\[
\begin{bmatrix}
\text{level}_{\text{Cat}} : \left[ \begin{array}{c}
M \equiv M \rightarrow \sigma \\
\end{array} \right] \\
\text{level}_{\text{Salt}} : \left[ \begin{array}{c}
\sigma \equiv \sigma \leftarrow M \\
\end{array} \right]
\end{bmatrix}
\]

Diamond: \( [1, 4, 2, 2] = (1 \text{ diamond with 4 order, 2 exchange and 6 coincidence relations}) \).

\[
\text{Diamond}^{(3,1)} = \chi \left[ \text{Cat, Salt, } M, \sigma \right]
\]

\[
\begin{bmatrix}
\text{level}_{\text{Cat}} : \left[ \begin{array}{c}
M \equiv M \rightarrow \sigma \\
\end{array} \right] \\
\text{level}_{\text{Salt}} : \left[ \begin{array}{c}
\sigma \equiv \sigma \leftarrow M \\
\end{array} \right]
\end{bmatrix}
\]

Diamond plus: \( [1, 8, 6, 6] \), plus simil relations (cf. ConTeXtures)
The wording with chiastic constructions is not simply "types becomes terms and terms becomes types" as in a traditional chiasm but "a type as a term becomes a term" on a different level and, at the same time, "a type as type remains a type" on the same level. Thus, a type as a term becomes a term and as a type it remains a type. And the same round for terms.

Thus, a type has two functionalities at once, a type as a type and a type as a term.
Therefore, this double meaning has to be distributed over different localization of the complex constellation.
Diamond Disremption

Diamond interpretation of the kenomic succession operation

Rudolf Kaehr Dr.
ThinkArt Lab

Abstract
Diamond interpretation of kenomic succession.
Kenomic disremption and equality in contrast to semiotic, category and diamond theory.
Diamondization of the concept of explanation and hermeneutic circles. Complementary commutativity.

1. Diamondization of kenogrammatics

1.1. Descriptive interpretation of disremption

Iteration and accretion
In contrast to the successor operation in word algebras, the operation of disremption, with its two aspects of iteration and accretion, is always defined by the simultaneity of a retro-grade and a progression action.

\[ S_{\text{iter}}(k_1 k_2 \ldots k_n) = (k_1 k_2 \ldots k_n) \oplus [i], \quad 1 \leq i \leq n \in \mathbb{N} \]
\[ S_{\text{acccr}}(k_1 k_2 \ldots k_n) = (k_1 k_2 \ldots k_n) \oplus [k_{n+1}], \quad n \in \mathbb{N} \]

Disremption in kenogrammatics seems to be an operation which is defined by a simultaneous interplay of retro-grade and progressive interactions.
If we take this double-movement of the kenogrammatic succession into account a reasonable formalization of it might be given by the diamond approach.

Retro-grade progression
A word arithmetic approach, as it was developed in several papers, is still result-oriented and is not reflecting on the double movement of the construction as such. Thematization of this kind of double-movement of retro-/progression (recipatory/anticipatory) is guided by an interactional approach which gets its formalization within the diamond model.

**Self-referentiality**

Self-referential parts of the recursion scheme are thematized. The recursion scheme gets a self-reflectional thematization.

**Chiastic interplay**

Circularity of self-referential structures gets a chiastic interpretation.

**Diamond interaction**

Double movements of chiastic implementation gets a diamond formalization. In which sense are kenogrammatic operations diamondal and interacting with bi-objectional structures?

### 1.2. Semiotic Concatenation

Concatenation for word arithmetic is defined by a recursion which is involving its pre-ordered alphabet (sign repertoire) $\Omega$.

$$\Omega = \{ k_1, k_2, \ldots, k_i, \ldots, k_n \}$$

Independently of the sign sequence $k$, a new sign out of the pre-given alphabet $\Omega$ is added to it. Hence the number of successors is depending on the size of the alphabet and not in anyway on the structure of the predecessor sign sequence.

Semiotic succession is defined in strict analogy to the concept of number-theoretic recursion.

There is also a kind of circularity in the recursive definition of succession: concatenation is introduced as addition and addition is introduced as succession. Because disremption is not relying on an alphabet, the number of successions is strictly depending on the structure of the kenogrammatic compound of the disremption operation.
**Circularity of Atomic Equality**

Signs are based in perception. There is no chance for semiotics to proof the identity of two atomic signs. The whole game of type and token of signs is not producing more than a circular introduction of signs. Two signs are equal if they are equiform. And two signs are equiform if they are equal in all there (graphemic) parts. And the parts of two signs are equal if they are equiform. Etc.

Hence, the objectivation of the sign process has stopped on the half way to subject independendness. For semiotic systems to work means to be founded in subjective perception. Computer science knows this dilemma as paradox of “Symbol Grounding”.

Therefore, A. A. Markov introduced his “Abstraction of identification” into algorithm theory, i.e. semiotic economy.

**Semiotic Equality**

Again, the equality of two words in a semiotic system is established by the graphemic identity (equality) of the signs at the same locality (position) of the compared words.

\[ \text{SemioticEquality} : \]
\[ \text{Seq}_x \text{ equiv Seq}_y \iff \forall i, j \in \text{Seq}_{x,y}, : \text{loc}_i = \text{loc}_j \land \text{loc}_i (\text{atom}_x) = \text{loc}_j (\text{atom}_y). \]

Or:
\[ \text{Seq}_x \text{ equiv Seq}_y \iff \forall i, j \in \text{Seq}_{x,y}, \]
\[ \text{length} (\text{Seq}_x) = \text{length} (\text{Seq}_y) \land \forall i, j \in \text{Seq}_{x,y} : \text{loc}_i (\text{atom}_x) = \text{loc}_j (\text{atom}_y). \]

The fact of the identification of position and identity of signs has a very clear consequence for the equality of two sign sequences (words). Two words with different length are semiotically unequal. Or, two sign sequences can be equal if and only if they are of equal length.

Hence, the radical challenge to graphemtical systems is the madness to crack exactly this presumption of equality. That is, the equality (similarity, dissimilarity) of kenomic patterns (morphograms) is independent of the length (complication) of the patterns to be compared. That is, two kenomic “sequences” (morphograms) might be kenomically equal independently of the length of the morphograms. Morphograms of different length might be kenomically equal.

**How is this possible?**

Semiotic sequences are equal iff they are decomposable into equal atomic signs, i.e. iff they are atomically equiform and of the same number.

If we take the idea of decomposability as the leading strategy for a comparison of sign systems or morphograms we can abstract from the sign repertoires and the singularity of the successor operation. Hence, the test of equality is based on decomposability.

This leads to the observation:
**Morphograms are kenomically (morphogrammatically) equal iff they can be decomposed into equal monomorphies.**

**Morphograms are kenomically (morphogrammatically) equal iff they have the same decomposition.**

Morphograms, as well as sign sequences, are composed, thus decomposition is the dual operation of composition. But duality can have different attributes. The main attributes might be symmetry and asymmetry of the duality operation.

**Semiotically**, composition of parts to a word and decomposition of the word into its parts are symmetric. That is, the inversion of the composition, the decomposition, results into the same parts of the composition, i.e. the operation of composition and decomposition are commutative:

\[ \text{Comp(Dec}(X^{(m)}) = \text{Dec(Comp}}(X_1, ..., X_m)). \]
1.3. Kenomic Disremption

1.3.1. Categorical interpretation

The categorical thematization of the successor operation is characterizing its structure “up to isomorphism”.

<table>
<thead>
<tr>
<th>1</th>
<th>N</th>
<th>N</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>↓f</td>
<td>↓f</td>
</tr>
<tr>
<td>g</td>
<td>↓</td>
<td>↓</td>
</tr>
<tr>
<td>A</td>
<td>N</td>
<td></td>
</tr>
</tbody>
</table>

A natural number object consists of an object and two
morphisms

0: 1 --> N, s: N --> N

such that for all objects A and all morphisms g, h
g: 1 --> A, h: A --> A there exist a unique morphism
f: N --> A making commute the diagramm NN.

1.3.2. Chiastic interpretation

I cannot deny that I was never really happy with the categorical introduction of the natural numbers (up to isomorphism). It looks good but I think it gives us only half of the story. That is, natural numbers N are defined with the help of other objects A which themselves are not defined with the help of the objects N of the whole construction. There is a hierarchy between the defined objects N and the means of the definition, the objects A. This is correct and adequate for an introduction or definition. That is, the hierarchy of the definition scheme is preserved.

But it is unnecessarily hierarchically one-sided. The fact, that the construction is involved into morphisms between the objects is not in conflict with my observation. The defining morphisms g, h are founding the object N in one and only one direction.

**Definition scheme:**
definition = Defiindiens --> definiendum.

(Definiens := That which defines the definiendum in a definition. Definiendum := The term defined in a definition.) Definitions are hierarchic but the definition scheme gets a circular introduction (definition).

Therefore, commutativity of the categorical diagram NN is only the half of the graphematic construction. The other half is sublimed in the mind of the reader.

A further step to understand and introduce natural numbers in the framework of category theory is to contemplate on the chiasm between the “object-” and the “medium-language” or source- and target-concepts.

A formalization of the chiastic interplay of “source-” and “target-concepts” might be designed in a polycontextural framework.

A chiasm between object- and medium-language to characterize diamondally natural numbers as a complementarity of commutativity in categories and in saltatories is distributed over two loci. The aim of this interplay is to characterize natural numbers, hence, there is a third locus required, the locus of the natural numbers as such. That is as the product of the foundational or constructional actions.

It seems that a logification of the diamondal interplay, necessary to handle the characterization of
the natural numbers logically, is demanding for a 3-contextural logic.

A more concrete phenomenological description should take into account that the number system involved in the classic modelling isn’t a number system but acts as a number system to be legitimated. These, not yet legitimated natural numbers are based on the intuition and the pre-understanding of natural numbers. That is, the whole construction as such is characterizing natural numbers, thus it gets a third locus of final inscription. Classically, it seems, that this third inscription is left to the mental imagination of the reader, i.e. the mathematician. And has no realization as an inscription.

**Again, what’s the profit?**
The existing paradigms are working! We have found water on mars! There is nothing wrong with our universal approach to natural numbers! Children, robots and Aliens do it!

If it is correct that the main part of the introduction mechanism for natural numbers is depending on a mental representation in the understanding by a mathematician and not on a scriptural notation in a textual space, i.e. on inscription, then there is no hope to create Artificial Intelligence capable of doing arithmetic as arithmetic and not of doing arithmetic as physical manipulations on informatical objects depending on the mental decisions of mathematicians or programmers.

The project of implementing subjectivity into the formalism - “Das Ich in den Formalismus hinenin definieren.” (Gunther 1937) - has nothing to do with the AI and AL intentions to add empirical features of human behaviors to artificial living systems.

**1.3.3. Diamond interpretation**

A more direct formalization of the chiastic concept of the categorical introduction of natural numbers (or other structures) is designed as a diamond interplay between the two complementary aspects of the construction.

Because of the complementary character of diamond theory, commutativity of constructions have to take into account the simultaneous complementarity of commutativity. Hence, a construction is specified only iff both diagrams, the categorical and the saltatorial, commutes.

**Parallelism of differentness, differentness and antidromic directions**

\[
\begin{align*}
A & \xrightarrow{h} A \\
g \swarrow & \uparrow f & \uparrow f \\
1 & \overset{\circ}{\xrightarrow{N}} & N & \overset{g}{\xleftarrow{N}} & 1 \\
1 & \overset{\circ}{\xrightarrow{N}} & N & \overset{\circ}{\xleftarrow{N}} & N \\
g \swarrow & \downarrow f & \downarrow f \\
A & \xrightarrow{h} A
\end{align*}
\]
While the process of succession goes forwards, at once it goes backwards. The step forwards can be done only in cooperation with a step backwards.

This step backwards is not a subtraction but a consultation of the history of the previous steps done to produce the morphogram to be succeeded.

To go forwards, we have to go backwards. This sentence might be interpreted in a temporal order as “to go forwards we first have to go backwards and then forwards”. This may be correct from an observational point of view. But it is not adequate from a conceptual viewpoint. From this, both actions happens at once. Forwards and backwards “movements” are interdependent. In a kenomic succession there is no need to go backwards without going forwards, and there is no forwards movement needed without its complementary backwards movement (Fichte, Husserl, Derrida).

Semiotically, this situation is strictly separated between the pre-given sign repertoire, which as a set of signs has its independent role, and the successor operation defined on the set of signs.

**Semantic composition**

Composition of two sentences is not necessarily a semantic concatenation of two separated and context independent units, like “car” and “parc”. But the term “parc” gets a specification in a composition with the term “car”, which is changing its former separated literal meaning. Hence, \( \text{comp}(\text{"car"}, \text{"parc"}) \rightarrow \text{"car parc"} \).

By composing two sentences, i.e by adding one semantic unit to an existing semantic unit a retrograde determination of the first unit by the new composition might happen. That is, the first unit gets its further semantic distinction by the additional semantic unit which is adding not only a new semantic unit to the first but is also adding specification to the definition of the context of the first semantic unit.

**Explication, explanandum, explanans**

Hence, explanations in general, might be given an antidromic interpretation as defining backwards the explanandum by adding forwards the new explanans.

“By the *explanandum*, we understand the sentence describing the phenomenon to be explained (not that phenomenon itself); by the *explanans*, the class of those sentences which are adduced to account for the phenomenon” (p.152).

The crucial comment, with respect to the scientific method, is given as follows:

"It may be said... that an explanation is not fully adequate unless its explanans, if taken account of in time, could have served as a basis for predicting the phenomenon under consideration.... It is this potential predictive force which gives scientific explanation its importance: Only to the extent that we are able to explain empirical facts can we attain the major objective of scientific research, namely not merely to record the phenomena of our experience, but to learn from them, by basing upon them theoretical generalizations which enable us to anticipate new occurrences and to control, at least to some extent, the changes in our environment” (p.154). (WiKi)

The logical problems involved in the explanation of the process of explanation had been a hot topic in the coffee houses of the famous Viennese time.
**Diamond Explanation Scheme**

![Diagram of the hermeneutical circle]

The hermeneutics circle
Such structures are also known as hermeneutical circles between pre-knowledge and knowledge.

"The hermeneutic circle describes the process of understanding a text hermeneutically. It refers to the idea that one's understanding of the text as a whole is established by reference to the individual parts and one's understanding of each individual part by reference to the whole. Neither the whole text nor any individual part can be understood without reference to one another, and hence, it is a circle."Wiki

A diamond interpretation can be given to the concept of explication and the concept of the *hermeneutic circle*. First, the metaphor of circle (or even feedback loop) shall be transformed into polycontextural chiasms, second chiasms shall be transformed into diamonds.

### 1.4. Diamond modeling of hermeneutics

#### 1.4.1. Circle

Well known is Martin Heidegger’s metaphorics of the circle: “Im Wirbel des Denkens”.

One of the famous opposites of the Wirbel is the “Strudel”, a multi-layered Viennese cake, a favorite of Rudolf Carnap.

„Die Idee der Logik selbst löst sich auf im Wirbel eines ursprünglicheren Fragens.“ (Martin Heidegger, Was ist Metaphysik., 1929, S. 37).

Despite the circularity of the hermeneutic concept of understanding there is still a chance for a conflict about the beginning of the circle. Should it be the whole or the part?

The metaphor of the “Wirbel” is not offering any chances to grasp at once the part and the whole as heterarchically organized components of the circular concept of understanding. In fact, the metaphor “Wirbel” easily hints to a hierarchy towards a final ground (Abgrund, Urgrund, Ungrund).

Hermeneutics is denying the possibility of formalization and thus is depending on the linearity of notional analysis of all sorts.

#### 1.4.2. Chiasm

Hermeneutic circle = [Text, Understanding, Whole, Part]

Even if the question of the beginning of the chiastic interdependency of the whole and parts of the process of hermeneutical understanding has a resolution, the figure produced is still uni-directional albeit it can be read explicitly in both directions: first part then whole and then first whole then part.

With that, the general circularity is getting a differentiated structuration which lacks circularity as “Wirbel des Denkens”.

#### 1.4.3. Diamond

Diamonds are implementing both directions of understanding at once. Hence, the metaphor is no longer given with a non-ambiguous and identifiable figure. It seems, that only the diamond approach resists any reduction to a more classical paradigm.
Obviously, all three constructions, Circle, Chiasm, Diamond would disappoint Rudolf Carnap and provoke a final destruction of the whole project of diamondization. Unfortunately, in between, mathematical logic itself has run into troubles.

1.5. Diamond explication of natural numbers

Chiastified circular strategies like explanation and hermeneutical circles might add to the understanding of the diamond strategic introduction of natural numbers.

```
A \xrightarrow{N} A
\exists \circlearrowleft f \quad \circlearrowleft f
\begin{bmatrix}
1 \circlearrowleft N \circlearrowright N \\
1 \circlearrowright N \circlearrowleft N
\end{bmatrix}
\text{with}
\begin{bmatrix}
1 \circlearrowleft N \circlearrowright N \\
1 \circlearrowright N \circlearrowleft N
\end{bmatrix}
= \begin{bmatrix}
1 \circ N \circ N \\
1 \circ N \circ N
\end{bmatrix}
```

A proper analysis of the diamond construction of the antidromic “movements” of natural numbers based on the difference relation in diamonds is given by a modeling of it in an explicit diamond with its chiastic properties. What was at first a diamondal difference operation is now involved into the full relational conceptionality of diamonds.

```
\text{Diam}(2.1) = \chi[\text{Cat}, \text{Salt}, \text{NN}, \text{AA}]
```

1.6. Initial and final objects in diamonds

2. Kenomtic sameness

2.1. Semiotic identity

\text{Sign}(A) \equiv \text{sign}(B): \text{type}(A) \text{id} \text{ type}(B) \text{iff for all token: token}(A) \text{id} \text{token}(B)

2.2. Monomorphic equivalence

Two kenomic patterns are equal iff they are decomposable into the same monomorphies.

Two kenomic patterns are equal iff they have the same monomorphic decomposition.

2.3. Chiastic sameness

\text{chiasm}(\text{typeA}, \text{typeB}, \text{tokeA}, \text{tokenB})

2.4. Diamond strangeness
diam(cat(A, B), salt(a, b))

Notes

2  http://www.thinkartlab.com/pkl/media/Equality/Equality.html
Abstract
Some preliminary remarks about an interplay of semiotic and graphematic diamonds are sketched. A reconstruction of Alfred Toth’s semiotic constructions of diamonds with the help of different notations is introduced. A distinction between the diamond properties of basic semiotic configurations and the composition of semiotic configurations as micro- and macro-analysis is proposed. The as-abstraction for semiotic connections is introduced and a mechanism to complement semiotic figures is proposed.

1. Mathematical semiotics and diamonds

1.1. Semiotics, again?
Thanks to the recent work of the semiotician Alfred Toth about mathematical semiotics and its application to polycontextural and kenogrammatic concepts, like chiasms and diamonds, a chapter of semiotization of diamonds and a diamondization of semiotics has to be added to the project of Short Studies.

This is a very first response to the profound work of Alfred Toth. It takes me back to the 70s/80s when I got involved in this headaching adventure of confronting Bense’s semiotics with Gunther’s polycontextural logic and kenogrammatics, both, at this time, quite in status nascendi, especially Gunther’s project.

Semiotics is defined by Peirce and is elaborated in extenso by Bense and Toth as a triadic-trichotomic system of semiosis, i.e. as a scheme of generating signs. Obviously, it has not to be confused with other sign theoretical projects, like semiology (de Saussure, Barthes) or the pre-war Semiotik for formal systems by Manfred Schröter and Hans Hermes.

Diamonds are not triadic-trichotomic but genuinely tetradic, chiastic, antidromic and 4-fold. Hence, diamonds are not semiotical

Are semiotic diamonds semiotical?

First diamondization: internal or micro
The semiotic sign relation is a product of semiosis which can be modeled as a categorical composition of elementary sign relations. Hence, a diamondization of semiotics is a diamondization of the semiotic composition operation of elementary sign relations. This kind of diamondization shall be called internal (micro) diamondization in contrast to the external (macro) diamondization of the composition of full sign systems.

Basic work to the study of diamonds of elementary semiotic compositions had been published by the semiotician Alfred Toth.
Toth gives a solution for the diamondization of sign systems with the help of the inversion operation (INV) he introduced.
Second diamondization: external or macro
A second kind of diamondization is introduced with the diamondization of the composition of signs as it occurs, i.e. in the constructions of iterative and accretive compositions of sign schemes, e.g. superposition and superisation of signs.

Transpositions, dualizations, inversions and compositions are semiotic operations, diamondization consists of difference, saltisitions, bridges and complementarity.

1.2. Toth’s semiotic diamonds
The semiotic composition operation of the elementary semiotic mappings, like (I->M), (M->O), (I->O), between the objects I, M, O, is commutative and associative. And obviously the identity mapping id is realized for the objects I, M, O.
Hence, semiotic composition can be studied as a mathematical category in the sense of category theory with objects I, M, O and its mappings (arrows) between the objects.

In concreto, it still has to be analyzed how the semiotic matching conditions for compositions are realized.
In the example above, the question is, how is “2.1” in (3.1 -> 2.1) as a codomain and in (2.1 -> 1.3) as a domain defined?

The new question which arises for abstract diamond theory is: How are the difference relations and hence the hetero-morphisms defined in concreto?

The papers of Toth are filling this gap with his semiotic modeling of diamonds.

Toth is suggesting an answer to the question, how to interpret the difference relations, with the introduction of the operation of inversion INV of a concrete sign scheme. Hence, Toth’s interpretation of diamonds is joining together semiotic and diamond thematizations and notational systems.

Inversion
Where is this operation INV from?

The sign relation ZR is defined as a relation of monadic, dyadic and triadic relations:
ZR = (a, (a==>b), (a==>b==>c).

Sign values for ZR are:
a = \{1.1, 1.2, 1.3\}
b = \{2.1, 2.2, 2.3\}
c = \{3.1, 3.2, 3.3\}
ZR = <3.x, 2.y, 1.z> with x,y,z ∈ \{1,2,3\} and x<=y<=z.

It is clear, that the semiotic inversion operation INV is a semiotic operation based on the elementary operations of transpositions and is not leading out of the semiotic domain.
INV is defined by:
INV(a.b c.d e.f) = (e.f c.d a.b).

In contrast, dualization is defined as:
DUAL(a.b c.d e.f) = (f.e d.c b.a).

The abstract sign scheme gets an interpretation by the introduction of the instances:
I = interpretant, M=medium and O=object.

Hence, the semiotic triad occurs as morphisms between the instances I, O, M and their combinations, called graph theoretic sign models.

1. (I-->O-->M) 4. (O-->M-->I)
2. (M-->O-->I) 5. (I-->M-->O), (M-->I-->O)
3. (I-->M-->O) 6. (O-->I-->M).

It is proposed by the Stuttgarter School of semiotics (Bense, Walter) that those triadic sign
schemes can be composed by their dyadic relations (mappings). Most of the semiotic work is in German, thus it is easily possible that I will miss the correct terminology.

Example:
2. \((M \Rightarrow O) (O \Rightarrow I) = (M \Rightarrow O \cdot O \Rightarrow I)\)

Hence, triadic-trichotomic sign relations are compositions of \textit{dyadic-dichotomic} relations. This is a strong thesis, and I don’t see the necessity of such a reduction.

Even more problematic, Elisabeth Walter (1979, S. 79), speaks of a \textit{lattice theoretical} union of \textit{“}(M \Rightarrow O) (O \Rightarrow I) = (M \Rightarrow O \cdot O \Rightarrow I)\textit{”}. (Toth, (2008b), p.11)

Bense (1976) is mentioning a \textit{category theoretical} composition of the triadic sign conceived as a transition from the set theoretic and relational definition to a more adequate presentation (Darstellung) of semioticity.

In the following, I will first follow this strategy, then I will focus on the composition of triadic-trichotomic sign structures as such.

The diamondization of the internal relations of signs might be called \textit{micro-analysis}, the focus on the latter \textit{macro-analysis} of semiotic diamonds.

These 6 graph theoretic sign models of I, O, M, get an interpretation by their corresponding numeric value occupancies.

Example

3.1 \((I \rightarrow O \rightarrow M)\)

\[
\begin{array}{ccc}
3.1 & 2.1 & 1.1 \\
(3.1 & 2.1 & 1.2) & (3.2 & 2.2 & 1.3) \\
(3.1 & 2.2 & 1.2) & (3.2 & 2.3 & 1.3) \\
(3.1 & 2.2 & 1.3) & (3.3 & 3.2 & 1.3)
\end{array}
\]

(Thot, p. 2, 2008a)

The new question which arises now is: How are the \textit{difference} relations of the semiotic diamond and hence the hetero-morphisms defined \textit{in concreto}? More precisely, how are the difference relations between the domains/codomains of morphisms and hetero-morphisms of semiotic composition defined? And is the inversion \textit{INV} operation strong enough to define the differentness of the new hetero-morphisms?

A \textbf{semiotic diamond by Toth}

Semiotic diamond for \((3.1 2.1 1.3)\) with

\[
\text{INV}(3.1 2.1 1.3) = (1.3 2.1 3.1)
\]

\[
dff(2.1_\omega) = (1.3)
\]

\[
dff(2.1_\alpha) = (3.1)
\]

\[
(3.1_x \rightarrow 2.1_\omega) \parallel (2.1_\omega \rightarrow 1.3_\omega) : \text{ composition}
\]

\[
(3.1_x \rightarrow 1.3_\omega) \parallel (1.3 \leftarrow 3.1) : \text{ acceptance \ parallel rejection }
\]

\[
(3.1_x \rightarrow 1.3_\omega) \parallel (1.3_\omega \rightarrow 3.1) : \text{ diamond result}
\]

In general, the sign class \((3.a \ 2.b \ 1.c)\) and its inversion \textit{INV}(3.a 2.b 1.c) = (1.c 2.b 3.a) are the components for the composition of semiotic diamonds (Thot, p.1, Saltatorien, 2008b).

Toth’s presentation of the micro-structure of a semiotic diamond and additional notational explications.
1.3. General micro-structure of semiotic diamonds

Adjunction

"Adjunktion ist eine Zeichenoperation mit reihendem, verkettendem Charakter" (Bense und Walther 1973, S. 11).

Superisation

Iteration

"Iteration ist eine Operation, die alle Teilmengen des Zeichenrepertoires gewinnt, als Potenzmengenbildung darstellbar ist” (ibid., S. 46).

The global sign relation or sign scheme seems to be ruled by an interplay of iteration, superisation and adjunction. Those operators are defining the complexity and complication of a composed sign structure. Unfortunately, the semiotic literature is not giving much information about their definition and how their internal mechanism is working. (Cf. Toth, pp.14-15, 2008a)

2. General macro-structure of semiotic diamonds

2.1. Dyads and triads (n-är vs. n-adisch)

The above considerations about formalization strategies for semiotics are supposing the possibility of composing the triadic-trichotomic sign relation out of dyadic sign relations. This is a common approach and might go back to Elisabeth Walter. Are triads, composed by dyads, still those highly privileged objects Peirce tried to introduce into mathematics with his trichotomic mathematics and trichotromic semiotics? Schroeder has written his famous book about relations on the base of dyadic relations. And from this point of view it is easy to proof that all n-adic relations can be reduced to binary relations. But Peirce wasn’t in love with dyads but with triads.

Metacritics

Metatheoretical comments to Toth’s mathematical semiotics as well as to the complex Bense/Walter is simply this: it is mathematical. Mathematics is not triadic-trichotomic, hence all
the applications of set theory, logic, category theory, etc. are artificial. As long as this situation would be critically reflected in the semiotic studies it would be adequate as a kind of modeling, simulation and formalization. But this is not the case! All such simulative applications comes with Bense’s scholastic authority. Hence, this strategy is sabotaging its own intention of developing a complex system of semiotics.

Nothing is changed with the involvement of the so called “qualitative mathematics” (Kronthaler, Toth). Not only because the dichotomy of quantitative/qualitative is Aristotelian but as a consequence, most operators introduced are “quantitative” per se. Even worse, there is no such thing as a ‘quantitative mathematics’. There is nothing “quantitative” with group and set theory and much less with category theory.

2.2. Semiotic operations

It seems that a more genuine semiotic approach to diamondize the semiotic sign relation might be introduced not as an internal reflection inside the sign definition but as an operation between signs as such. That is, the unary or binary (bivariate) operation of adjunction, superisation and iteration as a starting point leads to interesting diamond constructions.

Adjunction, superisation and iteration are operations on the general sign model \((O, I, M)\). Such unary operations, like successor operations, can be set into a binary formulation, i.e. as adding an element to an existing element or complexion. This addition, concatenation or composition can be specified as adjunctive, superitative and iterative. All 3 types of compositions have to fulfill their matching conditions to enable the specific composition. Such a specification is considering the internal structure of the sign, depending on its I, O, M constellations (cf. Toth’s “Makrosemiotische Zeichenzusammenhänge”). But operations as compositions or combinations can be understood as diamonds, i.e. as having the acceptional composat and its rejectional sign as results.

**General diamond combination scheme**

\[
O_{\text{Op}_{\text{diamond}}} \left( \text{sign}_1, \text{sign}_2 \right) = \overline{\text{sign}_3, \text{sign}_4}
\]

\[
\text{sign}_1 = \left[ O, I, M \right]_1
\]

\[
\text{sign}_2 = \left[ O, I, M \right]_2
\]

\[
\left[ \overline{\text{sign}_1, \text{sign}_2} \right] = \left[ \text{sign}_3, \overline{\text{sign}_4} \right]
\]

2.3. Semiotic monadic sign compositions

Matching conditions for monadic sign compositions:

\[
X = X', \text{ with } X, X' \in \left\{ I, O, M, \bar{I}, \bar{O}, \bar{M}, \bar{M}' \right\}
\]

Semiotic examples are taken from: (Toth, 2008a)

**Example:** 3.1.2.1. \(M \equiv M'\) (Toth, p. 20, 2008a)
\(3.1.21 \text{ M} = \text{M} \)

\[
\begin{array}{c}
\text{O, I, N} \circ \left(M', I', O'\right), \text{ with } \text{MC} = \text{M} = \text{M}' \\
\left(\text{O, I, MN', I', } \square \right)
\end{array}
\]

\[
\Pi_{\text{Type 1}}^{[2]} \left(\begin{array}{c}
\text{O} \\
\downarrow
\end{array} \right) \left(\begin{array}{c}
\text{O}' \\
\downarrow
\end{array} \right)
\]

\[
\left[\text{O} \rightarrow \text{O}'\right], \left[\text{O} \rightarrow \text{O}'\right], \left[\text{I} \rightarrow \text{I}'\right], \left[\text{O} \rightarrow \text{O}'\right]
\]

**Example : 3.1.2. M' = M**

\[
\Pi_{\text{Type 1}}^{[2]} \left(\begin{array}{c}
\text{O} \\
\downarrow
\end{array} \right) \left(\begin{array}{c}
\text{O}' \\
\downarrow
\end{array} \right)
\]

\[
\left[\text{O'} \rightarrow \text{O'}\right], \left[\text{O'} \rightarrow \text{O'}\right], \left[\text{M'} \rightarrow \text{M'}\right], \left[\text{O'} \rightarrow \text{O'}\right], \left[\text{O'} \rightarrow \text{O'}\right]
\]
2.3.1. Semiotic complementations

Given monadic compositions complementations/supplementations/derivations of the compositions are naturally produced and interpreted as a kind of semiotic deductions. A reasonable complementation operation has to rely on the as-abstraction to build its matching conditions. The existing concept of matching conditions is object-based, i.e. the coincidence of domain and codomain is not yet ruled by the as-abstraction, which is a mechanism to redefine and re-frame the functionality of the encountered objects.

This approach of complementations leads to the question how the different matching types are inter-related. How, e.g. can Type A = C be generated from Type1, M = M'?

Toth (2008a) gives a complex classification of different semiotic constellations. Complementations of one type is generating other types, hence a complementation-based inter-relation between different semiotic constellations becomes accessible for further studies.

Transformation of semiotic structural types by the as-abstraction

As an example, Type1 M=M', if M=M', the matching condition for M=M' is naturally realized. If I becomes I'' and I' functions as M'' and M=M' becomes O' then the concept of matching conditions is involved into a different kind of interpretation than the is-abstraction. Thus, the object-related or set-theoretical interpretation of objects as domains and codomains is not flexible enough to deal such a situation. In other words, the simple categorical identity relation for objects id has to be replaced by a more complex operation.

Hence, a reframing of M=M' of Type1 is generating new matching possibilities and thus a transformation of Type1 M=M' to other existing or new semiotic constellation types. The additional matchings for Type1 M=M' are: 

{I''=I', M=M' = M', M'' = I'}, which are generating 

\[ I'' \quad M'M'\quad O' \]
Example

\[
\left[ \begin{array}{c}
1 \\
0 \\
M^1 \\
O^1 \\
\end{array} \right]
\]

First supplement of

\[
\left[ \begin{array}{c}
1 \\
0 \\
M^1 \\
O^1 \\
\end{array} \right]
\]

MC: \( M = M^1 \quad \Rightarrow \quad \{ = R, M = M^1 = O^2, M^2 = O^1 \} \):

\[
\text{supp}_{1}\left( \left[ \begin{array}{c}
1 \\
0 \\
M^1 \\
O^1 \\
\end{array} \right] \right)
\]

Second supplement of

\[
\left[ \begin{array}{c}
1 \\
0 \\
M^1 \\
O^1 \\
\end{array} \right]
\]

MC: \( M = M^1 \quad \Rightarrow \quad \{ = R, M = M^1 = M^2, O^1 = O^2 \} \):

\[
\text{supp}_{2}\left( \left[ \begin{array}{c}
1 \\
0 \\
M^1 \\
O^1 \\
\end{array} \right] \right)
\]

Compositions of supplements

a. \( \text{supp}_{3} = \text{supp}_{1} \oplus \text{supp}_{2} \):

\[
\text{supp}_{3}\left( \left[ \begin{array}{c}
1 \\
0 \\
M^1 \\
O^1 \\
\end{array} \right] \right) \oplus \left[ \begin{array}{c}
1 \\
0 \\
M^1 \\
O^1 \\
\end{array} \right] \]

\[
\left[ \begin{array}{c}
1 \\
0 \\
M^1 \\
O^1 \\
\end{array} \right] \]

\[
\left[ \begin{array}{c}
1 \\
0 \\
M^1 \\
O^1 \\
\end{array} \right] \]

\[
\left[ \begin{array}{c}

\end{array} \right] \]
The supplementation \( supplem_4 \) seems to saturate the possibilities of complementing figure Type 1 \( M = M' \). A saturation is achieved if all possible semiotic knots are connected. A saturated semiotic figure or constellation can then be reduced or it can be augmented in complexity by iterative and accretive operations. The labelling of the semiotic knots with \( I, M, O \) might be at first just arbitrary and only depending on the as-abstraction, e.g. \( (MM^1 O^2 M^3) \) reads as "\( (MM^1 O^2) \) as \( M^3 \)". Thus, different labelling decisions are possible.

**Redundant supplementation**

A saturated figure, like \( supplem_3 \), might iteratively augmented by \( supplem_4 \) as a redundant iteration of an existing sub-figure, say \( (I^2, M^3, O^3) \).

Redundant supplementation is based on a semiotic operation, which isn't common in semiotic literature. It is well based on the polycontextural as-abstraction. Hence, it enables to thematize semiotic objects "\( X as Y is Z \)". e.g. \( I \) as \( I^1 \) is \( (I^1) \), \( I as O^1 is (O^1) \), \( I as M^1 is (M^1) \) and \( O^1 \) as \( O^1 \), etc.

Hence, again, the category theoretic identity operation \( id \) of classical semiotics is transformed to a difference operation. Identity, i.e. the is-abstraction, derives naturally from the as-abstraction with "\( X as X is X \)".

\[
\text{Redundant supplementation diagram:}
\]

\[
\begin{array}{c}
\begin{array}{c}
\text{\( supplem_4 \) as redundant iteration of a sub-figure.}
\end{array}
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
\text{\( (MM^1 O^2 M^3) \) reads as "\( (MM^1 O^2) \) as \( M^3 \)".}
\end{array}
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
\text{Thus, different labelling decisions are possible.}
\end{array}
\end{array}
\]

**2.4. Diamond monadic sign compositions**

\[
\begin{array}{c}
\begin{array}{c}
\text{Type 1 monadic sign compositions.}
\end{array}
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
\text{\( (O, I, M) \circ (M^* \rightarrow I^* \rightarrow O^*), M = M' \)}
\end{array}
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
\text{\( (O -> I -> M) \circ (M^* -> I^* -> O^*), M = M' \)}
\end{array}
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
\text{\( (O -> I -> M) \circ (M^* -> I^* -> O^*), M = M' \)}
\end{array}
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
\text{\( (O -> I -> M) \circ (M^* -> I^* -> O^*), M = M' \)}
\end{array}
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
\text{\( (O -> I -> M) \circ (M^* -> I^* -> O^*), M = M' \)}
\end{array}
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
\text{\( (O -> I -> M) \circ (M^* -> I^* -> O^*), M = M' \)}
\end{array}
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
\text{\( (O -> I -> M) \circ (M^* -> I^* -> O^*), M = M' \)}
\end{array}
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
\text{\( (O -> I -> M) \circ (M^* -> I^* -> O^*), M = M' \)}
\end{array}
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
\text{\( (O -> I -> M) \circ (M^* -> I^* -> O^*), M = M' \)}
\end{array}
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
\text{\( (O -> I -> M) \circ (M^* -> I^* -> O^*), M = M' \)}
\end{array}
\end{array}
\]
\[ \Pi_{\text{Type c}}^{(2)} \text{MC: } \mathcal{M}_{\text{FF}} \downarrow \mathcal{O} \equiv \mathcal{O}' \]
\[ \begin{bmatrix} M^I \text{ } \mathcal{I}' \\ M \text{ } \mathcal{O}' \end{bmatrix} \bigg| \begin{bmatrix} M^I \text{ } \mathcal{I}' \\ M \text{ } \mathcal{O}' \end{bmatrix} \bigg| \begin{bmatrix} \mathcal{M} \leftarrow \mathcal{M}' \end{bmatrix} \bigg| \begin{bmatrix} \mathcal{O} \leftarrow \mathcal{O}' \end{bmatrix} \]
2.5. Dyadic sign compositions

2.5.1. Dyadic semiotic sign compositions

Matching conditions for dyadic sign compositions:

\[ MC : X \rightarrow Y \equiv X' \rightarrow Y' \text{, with } X, X', Y, Y' \in \{I, O, M, I', O', M'\} \]

Example: 3.2.2.1. M/O \equiv M'/O' (Toth, p. 33, 2008a)

\[
\Pi_{O \to O'}^{(2)} M \to M' I \to M' I \to M' \equiv \begin{bmatrix}
M & \circ & I \\
\circ & O' & I \\
I & I' & O'
\end{bmatrix}
\]

2.5.2. Diamond dyadic sign compositions

\[
(M \to I \to O) \circ (O' \to I' \to M') \text{ with } MC = M/O = M'/O'
\]
\[
(M \to I \to O) \circ (O' \to I' \to M') | (O \to O) \parallel (M \to M')
\]
\[
(O \to I \to M) \circ (M' \to I' \to O') \text{ with } MC = M/O = M'/O'
\]
\[
(O \to I \to M) \circ (M' \to I' \to O') | (M \to M') \parallel (O \to O')
\]
\[
(O, I, M) \circ_{M, O} (M', I', O') \text{ with } MC = M/O = M'/O'
\]
\[
(O, I, M) \circ_{M, O} (M', I', O') | (M \to M') \parallel (O \to O')
\]
a. \[
\begin{array}{c}
\text{Diamond Semiotics.nb file:///Volumes/KAE-TEXTE/KAE-TEXTS/Short%20Studies/Pub...}
\end{array}
\]
**Type 1 = 1:** \( MC : M = M', \ O' = M'', \ O'' = M'\) \(\) (Toth, p. 65, 2008 a)

\[
\begin{array}{cccccc}
 I & \square & \square & I' & \square & \square \\
\downarrow & \nwarrow & \downarrow & \nwarrow & \downarrow & \nwarrow \\
O & \rightarrow & M = M' & \rightarrow & O' = M'' & \rightarrow \ O'' = M'"
\end{array}
\]

\[
\begin{array}{c}
\left\{ O' \leftarrow M'' \right\} \\
\left\{ M \leftarrow M' \right\}
\end{array}
\]

**Type 1 = 1:** \( MC : M = M', \ O' = M'', \ O'' = M'\) \(\) \(\pi_{\{0, I, M\}}^{(3)}\)

\[
\begin{array}{cccc}
\square & I & \square & \square \\
O' & M' & M & O \\
\square & I' & M'' & \square \\
O' & \square & I' & \square \\
\end{array}
\]

\[
\left\{ M \leftarrow O'' \right\}
\]

**Type 1 = 1:** \( MC : M = M', \ O' = M'', \ O'' = M'\) \(\) \(\pi_{\{0, I, M\}}^{(3)}\)

\[
\begin{array}{c}
\left\{ O \rightarrow M, \ N' \rightarrow O', \ M'' \rightarrow O'' \right\} \\
\left\{ O \rightarrow O', \ M \leftarrow O'' \right\}
\end{array}
\]

**Type 4 = 4:** \( MC : I' \equiv O'', \ M \equiv M', \ M' \equiv M'', \ O \equiv I'\) (Toth, p. 65, 2008 a)

\[
\Pi_{\text{Type 4-4}}^{(4)} \left(\begin{array}{c}
O \\
\downarrow & \nwarrow \\
I & \rightarrow
\end{array}\right)
\]

\[
\begin{array}{c}
\left\{ O' \leftarrow O'' \right\} \\
\left\{ M \leftarrow M' \right\} \\
\left\{ M' \leftarrow M'' \right\} \\
\left\{ O \leftarrow I' \right\}
\end{array}
\]
**Type 1 ≡ 2:**

\[ MC : M = M', O = O", M" = M"' \]  

\[ \Pi_{\text{Type } 1=2} \]

\[
\begin{array}{c}
\begin{array}{c}
\circ \quad \circ \quad \circ \quad \circ \quad \circ \quad \circ \quad \circ \quad \circ \\
\downarrow \quad \downarrow \quad \downarrow \\
I \rightarrow M
\end{array}
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
\circ \quad \circ \quad \circ \quad \circ \quad \circ \quad \circ \quad \circ \quad \circ \\
\downarrow \quad \downarrow \quad \downarrow \\
O \rightarrow M \rightarrow M' \rightarrow O' \rightarrow O" \rightarrow M" \rightarrow M"' \rightarrow O
\end{array}
\end{array}
\]

**Type A ≡ A ≡ B:**

\[ MC_f : l' = l", M = M', O = O' = O" \]

\[ \Pi_{\text{Type } A = A = B}^{(4)} \]

\[
\begin{array}{c}

\]
2.6. Local-/global-heteromorphisms

Sign functions, understood as a composition of elementary sign relations are producing their local diamond structures according to the matching conditions of the compositions of elementary sign morphisms.

Sign systems, understood as combinations of sign functions are producing their global diamonds in accordance to the matching conditions of their combined signs.

As an interpretation, this semiotic difference of local and global or micro/macro diamond structures can be connected with the distinction of inner and outer environments of semiotic diamond systems.

**Micro – analysis of \(l, O, M\)**

\[

(M \rightarrow O')
\end{array}
\end{array}
\end{bmatrix} \]
Diamond semiotics

Diamond micro/macro – analysis of Type 4 = 4 (iter, acc)

Type 4 = 4 (iter)

\[ \Pi_{\text{Type 4 = 4}}^{(4)} \]

\[ \left( \begin{array}{c} M \rightarrow O \\ O \end{array} \right) \], macro

\[ \Pi_{\text{Type 4 = 1}}^{(1)} \]

\[ \left( \begin{array}{c} \text{O}^\prime \text{I} \text{O}'' \text{I}'' \\ \text{M} \rightarrow \text{M}' \text{M}'' \\ \text{I} \text{O}'' \text{O}^\prime \end{array} \right) \]

\[ \left( \begin{array}{c} \text{I}'' \rightarrow \text{O}^* \\ \text{M} \rightarrow \text{M}' \\ \text{M}' \rightarrow \text{M}'' \\ \text{O} \rightarrow \text{I}'' \end{array} \right) \]
Generalizations of the matrix or bracket notation should easily be accessible to develop a general notational system for semiotic diamonds.

**Diamond Theory** (Steven H. Cullinane) has many faces:
2.7. Composition of semiotic diamonds

A first analysis of the composition operation for semiotic diamonds results into an iterative and accretive or serial and parallel form of “2-dimensional” composition. These operators might correspond to the semiotic operations “adjunction”, “superisation” and “iteration”. As a further operation, a general reflection or mirror operation is necessary. Hence, a figure like Type 1 ≡ A might be written as a combination of iteration, \( \text{op}_{\text{iter}} \), accretion, \( \text{op}_{\text{acc}} \), and mirroring, \( \text{op}_{\text{mir}} \).

Each operation has to fulfill the matching conditions, MC, and is prepared to be involved into diamondization. Matching conditions are reflecting, externally, the composability of compositions, therefore they are represented as hetero-morphisms of saltatories. Both together, the categorical compositions with \( \text{op}_{\text{iter}} \), \( \text{op}_{\text{acc}} \), and \( \text{op}_{\text{mir}} \) and the heteromorphic representations of their combinations are building the diamond structure of the semiotic composition.

**Semiotic Figure Type 1 ≡ A (Toth. 2008 a, p. 79)**

\[
\left( \text{op}_{\text{acc}} \circ \text{op}_{\text{mir}} \circ \text{op}_{\text{iter}} \circ \text{op}_{\text{iter}} \left( \left[ \text{op}_{\text{iter}} \left( \left[ \text{op}_{\text{iter}} \left( \left[ \text{op}_{\text{acc}} \circ \text{op}_{\text{mir}} \right] \right] \right] \right] \right) \right) \right),
\]

reflecting the matching conditions:

\[
\text{MC} = \{ M = M', \; O = M'' = M''' = O'' = O''' \}
\]
Diamondization of Figure Type 1 ≅ A:

Type 1 ≅ A:

\[ \text{MC} : M \equiv M', \; O' \equiv M'' = M'''', \; O'' \equiv O''' \]

\( \Pi_{\text{Type } 1 \equiv A}^{(4)} \left( \begin{array}{c} l \rightarrow M \\ l'' \rightarrow M \end{array} \right) \), macro

\[
\begin{bmatrix}
I & I' & I'' & I''' \\
O & M & M' & M'' & O' & O'' & O''' & I'''' \\
\hphantom{O} & \hphantom{M} & \hphantom{O'} & \hphantom{O''} & \hphantom{O'''} & \hphantom{I''''} \\
\end{bmatrix}
\begin{bmatrix}
O'' \leftarrow O' \\
M'' \leftarrow M''' \\
O' \leftarrow M'' \\
M \leftarrow M' \\
\end{bmatrix}
\]

Matching conditions

\( \text{op}_\text{tor} : \text{MC} = \left( M \equiv M', \; O' \equiv M'' = M'''', \; O'' \equiv O''' \right) \)

\( \text{op}_\text{soc} : \text{MC} = \left( M'' \equiv M'''', \; O'' \equiv O''' \right) \)

\( \text{op}_\text{nr} : \text{MC} = \left( O' \equiv O''', \; M'' \equiv M''' \right) \)
3. Goguen’s semiotics: From Peirce to Pierce

A closer connection between trichotomic semiotics and mathematical category theory is accessible with Joseph Goguen’s work to the semiotics of Human-Computer-Interface (HCI) theory. This chapter is a preliminary hint to a new Short Story about the interplay of semiotics, category theory and diamond theory in respect to a theory of presentation, representation and evocation. It might then be seen as a late contribution to my old (German) project “Kalkül und Kreativität” (1998-2002).

Goguen, Semiotic Morphism, 1996/2004

Definition 1

A sign system, or semiotic system or semiotic theory, consists of:

1. a signature, which declares sorts, subsorts and operations (including constructors and selectors);
2. a subsignature of data sorts and data functions;
3. axioms (e.g. equations) as constraints;
4. a level ordering on sorts, including a maximum element called top; and
5. a priority ordering on constructors at the same.

The non-data sorts classify signs and their parts, just as in grammar, the "parts of speech" classify sentences and their parts. There are two kinds of operation: constructors build new signs from old signs as parts, while selectors pull out parts from compound signs. Data sorts classify a special kind of sign that provides values serving as attributes of signs. Axioms act as constraints on what count as allowable signs for this system. Levels indicate the whole/part hierarchy of a sign, with the top sort being the level of the whole; priorities indicate the relative significance of subsigns at a given level; social issues play a dominant role in determining these.

Definition 2

A semiotic morphism $M : S_1 \rightarrow S_2$ from a semiotic system $S_1$ to another $S_2$ consists of the following partial mappings:

1. from sorts of $S_2$ to sorts of $S_2$, so as to preserve the subsort relations,
2. from operations of $S_2$ to operations of $S_2$, so as to preserve their source and target sorts,
3. from levels of $S_1$ sorts to levels of $S_2$, so as to preserve the ordering relation, and
4. from priorities of $S_1$ constructors to priorities of $S_2$ constructors, so as to preserve their ordering relations, so as to strictly preserve all data elements and their functions.

It is easy to prove that this definition of composition obeys the following identity and associative laws, in which $A : R \rightarrow S$, $B : S \rightarrow T$ and $C : T \rightarrow U$,

- $A : 1_S = A$
- $1_S : B = B$
- $A : (B ; C) = (A : B) ; C$

where $1_S$ denotes the identity morphism on $S$. These three laws are perhaps the most fundamental for a calculus of representation, since they imply that semiotic theories and their morphisms form what is called a "category" in the relatively new branch of mathematics called category theory [Mac Lane, 1998].

The basic ingredients of a category are objects, morphisms, and a composition operation that satisfies the above three laws, and that is defined on two morphisms if and only if they have matching source and target.

Three of the simplest categorical concepts are isomorphism, sum and product. A morphism $A : R \rightarrow S$ is an isomorphism if and only if there is another morphism $B : S \rightarrow R$ such that $A ; B = 1_R$ and $B ; A = 1_S$, in which case $B$ is called the inverse of $A$ and denoted $A^{-1}$; it can be proved that the inverse of a morphism is unique if it exists. The following laws can also be proved, assuming that $A : R \rightarrow S$ and $B : S \rightarrow T$ are both isomorphisms (and no longer assuming that $B$ is the inverse of $A$).
1R⁻¹ = 1R
(A⁻¹)⁻¹ = A
(A ; B)⁻¹ = B⁻¹ ; A⁻¹

Because sign systems and their morphisms form a category, these three laws apply to representations.

http://www.cs.ucsd.edu/users/goguen/4mari/4mari.html

"The creative process is to some extent unpredictable and uncontrollable; this is more true of artistic creation than of design, but it holds for both. The best designs often seem both surprising and obvious, and they also often seem to come suddenly out of nowhere, but usually after a lot of hard work."

http://www-cse.ucsd.edu/users/goguen/papers/sm/node5.html#SECTION3-2

A sign theory of representation, as it is the case for the Peirceian semiotics, might well be conceptualized in its basic structure by the concepts and laws of mathematical category theory.

Also signs are introduced by Peirce as ‘representamen’, sign events haven’t to be restricted to the process of representation. Innovative and creative sign events are not representational. They are not re-presenting something existing but are creating something, which has not to be in any sense an ontological "something", which isn’t yet existing. Qualitative categories like “surprise”, “suddenly of nowhere”, “unpredictable”, etc. are not covered by category theory and category based semiotics. Categorical and semiotic compositions are conservative and save, not leaving the framework of their definition.

Neither is the New covered by the category of Becoming (Hegel, Lawvere).

"Thus I believe to have demonstrated the plausibility my thesis that category theory will be a necessary tool in the construction of an adequately explicit science of knowledge." (Lawvere, 1994, p. 55)

A new approach beyond the magic of inspiration and the mechanization of creation is proposed by the general diamond strategies.

"The possibility of being surprised is exhibited as the main argument for the existence of protentions. It is an observable fact, Husserl says, that we all can be at every moment suddenly surprised; now, in order one to be surprised, she must experience an unexpected event; therefore we have at every moment some expectation about the most immediate future. We anticipate the future whenever we are having intentional acts." (Julio Ostalé)

http://staff.science.uva.nl/~michiell/docs/Corrected%20Handout.pdf

"The harmonic My-Your-Our-Class conceptualization has to be augmented by a class which is incorporating the place for the other, the unknown, the difference to the harmonic system. That is, the NotOurClass is thematized positively as such as the class for others, called the OthersClass. Hence, the OthersClass can serve as the place where intruders, attacks, disturbance, etc. can be observed and defended. But also, it is the place where the new, inspiration, surprise and challenge can be localized and welcomed." (Kaehr, 2007)

Toth’s semiotic diamonds

Analyzing construction principles for semiotic diamonds

Rudolf Kaehr Dr.
ThinkArt Lab Glasgow

Abstract

A detailed comparison of Toth’s semiotic diamonds (Diamanten) and the diamonds of diamond category theory is presented. It turns out that Toth’s Diamanten are based on inversions of acceptional morphisms and are not constituting any rejectional morphisms. A proper definition of the matching conditions is missing. A comparison of the matching conditions for Diamanten and diamonds gives easy criteria for separation of the approaches. As a result, semiotic Diamanten are not working as semiotic models of categorical diamonds. Nevertheless, semiotic Diamanten are a novelty in semiotics and are opening up new fields of semiotic studies.

Sketch of Toth’s semiotics

The semiotic composition operation of the elementary semiotic mappings, like (I→M), (M→O), (I→O), between the objects I, M, O, is commutative and associative. And obviously the identity mapping id is realized for the objects I, M, O. Hence, semiotic composition can be studied as a mathematical category in the sense of category theory with objects I, M, O and its mappings (arrows) between the objects.

Categorical interpretation of the semiotic sign scheme

\[
\begin{align*}
  i.i &= idi, \ i = 1, 2, 3 \\
  1.2 &= \alpha \quad \equiv \quad \begin{array}{c} 1 \xrightarrow{\alpha} 2 \\
  1.3 &= \beta \alpha \quad \equiv \quad 1 \xrightarrow{\beta \alpha} 3 \\
  2.3 &= \beta \quad \equiv \quad 2 \xrightarrow{\beta} 3 \\
  2.1 &= \alpha^* \quad \equiv \quad 1 \xleftarrow{\alpha^*} 2 \\
  3.1 &= \alpha^* \beta^* \equiv 1 \xleftarrow{\alpha^* \beta^*} 3 \\
  3.2 &= \beta^* \quad \equiv \quad 2 \xleftarrow{\beta^*} 3 \\
\end{array}
\]

In concreto, it still has to be analyzed how the semiotic matching conditions for compositions are realized. In the example above, the question is, how is “2.1” in (3.1 → 2.1) as a codomain and in (2.1 → 1.3) as a domain defined?
The new question which arises for abstract diamond theory is: How are the difference relations and hence the hetero-morphisms defined in concreto?

I had the idea that the papers of Toth are filling this gap with his semiotic modeling of diamonds. But it turned out that there is a crucial difference between "semiotische Diamanten" and categorical diamonds. Therefore, there is still an open question about a semiotic concretization of categorical diamonds.

Toth is suggesting an answer to the question, how to interpret the difference relations, with the introduction of the operation of inversion INV of a concrete sign scheme. Hence, Toth’s interpretation of diamonds tries to join together semiotic and diamond thematizations and notational systems.

Inversion

Where is this operation INV from?
The sign relation ZR is defined as a relation of monadic, dyadic and triadic relations:

\[ ZR = (a, (a\rightarrow b), (a\rightarrow b \rightarrow c)) \]

Sign values for ZR are:
\[ a = \{1.1, 1.2, 1.3\} \]
\[ b = \{2.1, 2.2, 2.3\} \]
\[ c = \{3.1, 3.2, 3.3\} \]

ZR = \langle 3.x, 2.y, 1.z \rangle with \(x, y, z \in \{1,2,3\}\) and \(x \leq y \leq z\).

It is clear, that the semiotic inversion operation INV is a semiotic operation based on the elementary operations of transpositions and is not leading out of the semiotic domain.

INV is defined by:

\[ INV(a.b \ c.d \ e.f) = (e.f \ c.d \ a.b) \]

In contrast, dualization is defined as:

\[ DUAL(a.b \ c.d \ e.f) = (f.e \ d.c \ b.a) \]

The abstract sign scheme gets an interpretation by the introduction of the instances:
I = interpretant, M=medium and O=object.

Hence, the semiotic triad occurs as morphisms between the instances I, O, M and their combinations, called graph theoretic sign models.

1. (I \(\rightarrow\) O \(\rightarrow\) M) 4. (O \(\rightarrow\) M \(\rightarrow\) I)
2. (M \(\rightarrow\) O \(\rightarrow\) I) 5. (I \(\rightarrow\) M \(\rightarrow\) O), (M \(\rightarrow\) I \(\rightarrow\) O)
3. (I \(\rightarrow\) M \(\rightarrow\) O) 6. (O \(\rightarrow\) I \(\rightarrow\) M).

It is proposed by the Stuttgarter School of semiotics (Bense, Walter) that those triadic sign schemes can be composed by their dyadic relations (mappings).

Most of the semiotic work is in German, thus it is easily possible that I will miss the correct terminology.

Example:

2. (M \(\Rightarrow\) O) (O \(\Rightarrow\) I) = (M \(\Rightarrow\) O \(\Rightarrow\) O \(\Rightarrow\) I)

Hence, triadic-trichotomic sign relations are compositions of dyadic-dichotomic relations. This is a strong thesis, and I don’t see the necessity of such a reduction.

Even more problematic, Elisabeth Walter (1979, S. 79), speaks of a lattice theoretical union of “(M \(\Rightarrow\) O) (O \(\Rightarrow\) I) = (M \(\Rightarrow\) O.O \(\Rightarrow\) I)”. (Toth, (2008b), p.11)
Bense (1976) is mentioning a category theoretical composition of the triadic sign conceived as a transition from the set theoretic and relational definition to a more adequate presentation (Darstellung) of semioticity. 

In the following, I will first follow this strategy, then I will focus on the composition of triadic-trichotomic sign structures as such. The diamondization of the internal relations of signs might be called micro-analysis, the focus on the latter macro-analysis of semiotic diamonds. 

These 6 graph theoretic sign models of I, O, M, get an interpretation by their corresponding numeric value occupancies. 

**Example**

3.1 (I –> O –> M)

(3.1 2.1 1.1)  (3.1 2.3 1.3)
(3.1 2.1 1.2)  (3.2 2.2 1.2)
(3.1 2.1 1.3)  (3.2 2.2 1.3)
(3.1 2.2 1.2)  (3.2 2.3 1.3)
(3.1 2.2 1.3)  (3.3 2.3 1.3)
(Thot, p. 2, 2008a)

The new question which arises now is: How are the difference relations of the semiotic diamond and hence the hetero-morphisms defined in concreto? More precisely, how are the difference relations between the domains/codomains of morphisms and hetero-morphisms of semiotic composition defined? And is the inversion INV operation strong enough to define the differentness of the new hetero-morphisms?

---

### Response to Toth’s remark

**My question:** “Is the inversion INV operation strong enough to define the differentness of the new hetero-morphisms compared to morphisms?”

**Toth’s remark**

“In einer kürzlich veröffentlichten Kritik bemerkte Rudolf Kaehr zurecht, dass in dergestalt eingeführten semiotischen Diamanten die Heteromorphismen nichts anderes seien als Spiegelungen dyadischer semiotischer Funktionen (Kaehr 2008, S. 3).”

Kaehr übersieht allerdings, dass die Umkehrungen dyadischer Funktionen nur formal, aber nicht inhaltlich Spiegelungen sind. Z.B. bedeutet (2.1 => 3.1) die rhematische Interpretation eines Abbildes, aber die umgekehrte Funktion (3.1 => 2.1) muss, wie bereits Bense (1981, S. 124 ff.) bemerkt, nicht zum selben Icon zurückführen. Es kann sich hier also um einen echten semiotischen Heteromorphismus handeln.” [my emph]

**Response**

As far as I understand, Toth is pointing to the fact, that an inversion (Umkehrung, Spiegelung) of a morphism like (2.1 ⇒ 3.1) is not re-establishing the identity of “2.1” in concreto. In other words, the formal inversion of a dyadic function is not identical with its mirroring with regard to its content. Hence, with an inversion INV (2.1 ⇒ 3.1) = (3.1 ⇒ 2.1), the role of “2.1” might change from a rhematic interpretation of an object to a different interpretation of an object, not necessary the same icon.

The same is true for the inversion of morphisms in a category! But, nevertheless, category theory is studying morphisms and their inversions and duality in abstracto. The same is intended for diamond theory. Morphisms and heteromorphisms in diamonds are considered as abstract.

That’s a reason too, while Toth’s approach to diamonds is important: he offers a concrete interpretation. Hence, it also could be understood as a model for abstract diamonds. On the other hand, diamonds are instrumental to solve some intriguing problems of mathematical semiotics.

With my introduction of diamonds and their hetero-morphisms I tried to distinguish them from both, inversions and duals (opposites) of morphisms. It is well known, that an inverted, also dual, morphism is still a morphism for
which all the properties and laws for morphisms (identity, commutativity, associativity) of the category holds. While for hetero-morphisms, different laws are involved. And that’s the reason why they are called hetero-morphism and are belonging to saltatories and not to categories.

What I called antidromic direction of arrows for hetero-morphisms is not simply an inversion of the arrow of a morphism, and therefore still a morphism, but a new abstraction based on “difference” relations of the “targets” and “sources” of composed morphisms, i.e. of compositions. Hetero-morphisms are conceived as abstractions from the operation of composition and not from morphisms between objects. Even if those difference relations are considered as inversions, they have to take place at the right place, i.e. at the target of the first and at the domain of the second morphism of the composition of the morphisms.

This in full harmony to what I developed from the very beginning of the introduction of the diamond concept (diamond category theory, diamond theory, etc.).

The name “hetero-morphisms” might be misleading, but the formal definition is what counts and not its label. There is a different use of the term ‘hetero-morphism’ in my paper “Categories and Contextures”.

Because diamonds are introduced in an abstract way, i.e. depending on the alpha/omega-structure of composition of morphisms only, it is of importance to find reasonable examples as concretizations. An other interesting concretization is the attempt to introduce diamond relations as a diamondization of relation theory.

In this sense of concretization, I see the importance of Toth’s approach, albeit he is missing the train.

Unfortunately, after I finally understood Toth’s concept “semiotischer Diamanten” (semiotic diamonds) it turned out that Toth’s “Diamanten” are strictly different from my ‘diamonds’.

Hence, Toth has given some interesting interpretations for his “Diamanten” in the context of semiotics but not to my diamonds. That is, my hope for a semiotic concretization of the abstract mathematical concept of ‘diamond category theory’ has still to wait to be achieved.

Nevertheless, there are also creative misunderstandings! In this sense, both concepts, the “Diamanten” and the diamonds, are interesting topics. Toth’s “Diamanten” are, thus, a (creative) misinterpretation of my diamonds.

Hence, despite the examples for ‘semiotische Diamanten’, the relevant question still is: How are semiotic diamonds defined? Where are the properties, rules and laws? And, first of all, how are the difference relations introduced? There is surely an inversion operation in semiotics but there is no abstraction corresponding to the diamond difference relations or operations.

Semiotics is still depending on is-abstractions in contrast to as-abstractions in diamond theory.

**Diamonds, everywhere?**

Independent of the question of the motivation to mention that my teacher Gotthard Gunther had introduced diamonds long before my own humble trial, Toth’s move confirms clearly and without sophisticated manoeuvres of my interpretations what exactly he understands by a “Diamant” (diamond). Correctly, Toth understands by a Diamant the formal structure of a special square: ⊙. Unfortunately, not all such diamonds are diamonds in the sense of the diamond category theory I introduced recently. What counts in a mathematical theory are the definitions, properties and rules. The same holds for diamond (category) theory.

I’m quite convinced that my definitions, despite their tentativeness, are clear enough to show the difference between a ‘square’ concept and my diamond concept of an interplay between categorical and saltatorial arrows (maps, morphisms).

In other words, diamonds, labeled with some mighty labels might seduce to engage into a recreational game but are by no way of any interest for my own work, which stands without any ‘didactical’ figures.

The other hint to Toth’s diamond interpretation is given by his historical comments that I introduced myself the diamond approach first 1995 and then specially in 2007. I appreciate the honor I’m given for a figure, which is
known, at least outside polycontexturality, since tausends of years.

In fact, I’m turning around in this carousel at least, officially, since 1973-75 (published 1978), with my closed proemial relationship (“geschlossene proemial Relation”), which Gunther liked very much, albeit I didn’t see much to formalize.

It was written strategically against the Varela's ECI and the re-entry mysticism.

A university degree was achieved by my student Klaus Grochowiak with “Die formal Struktur der Zirkulation bei Karl Marx”, 1976, which is an intriguing application of diamonds, albeit labelled differently, and chiasms!

Then, the very first diamond approach for communicational purposes (and money making) was developed 1992 and was called, for a joke, “Das Existenz-Halma”. Halma is a board game. It worked! Why not? And again, I started a series of serious work about “Diamond Strategien” (1995-1998).

Without doubt, I’m very much aware about that, i.e. my own intellectual history. Too long to tell! It would be surprisingly strange or even highly cranky if I would have proclaimed 2007 that I discovered the diamond of category theory or diamond category theory, not knowing that I and especially Gunther introduced diamonds long before.

Again, the whole story is documented in my ‘Handbuch’ (1995)! I simply would like to recall Daniel Hellerstein’s Diamond Logic! Which nevertheless has nothing to do with diamond theory.

As often, misunderstandings might create some interesting results.
But scholasticism of some groups is forcing me to offer some clarifications.

Nevertheless, it is a merit of Alfred Toth to have done interesting work on the base of his concept of Diamanten and he has mentioned his source of inspiration as far as he has access to it.
On the other hand, I feel motivated to typset even more constructions.

Alfred Toth, Phantasie und Technik, 1.1.2009
**Toth’s general procedure**

"Die semiotische Rejektionsfunktion ist nun aber keineswegs auf den Strukturtyp (e.f.c.d.a.b) wie im obigen semiotischen Diamanten beschränkt. Semiotische Inversion (INV) ist allgemein durch folgende zwei Anweisungsschritte erreichbar:

2. Vertausche alle semiotischen Morphismen mit ihren *Inversen* (wobei natürlich z.B. $a^o = a$, $b^o = b$ und per definitionem (vgl. Toth 1993, S. 21 ff.) $(ba)^o = a^o b^o$ und $(a^o b^o)^o = ba$ gilt."

**INV - Rules**

I. $a^oo = a$, $b^oo = b$,
II. $(ba)^o = a^o b^o$,
III. id$^o = id$

$(a^o b^o)^o = (b^o a^o)^o = ba$ (IV.)

Hence, there are two steps to consider for the construction of a hetero-morphism in a semiotic diamond:

1. **Chiasm**: Change the order of subsigns.
2. **Inversion**: Exchange all semiotic morphisms with their inversion.

This can be reformulated by:

1. **Apply the inverse operation INV** to the parts $(A_3, B_3)$ of an (acceptional) morphism $(\text{morph}_3)$.
   An acceptional morphism is the composition of two basic morphism of a semiotic category.
2. **Substitute** the results of the *first* part, $(A_3)$, of the morphism with the *second* part, $(B_3)$, of the hetero-morphism, morph$^4$, to be constructed. And the same procedure with the *second* part, $(B_3)$; substitute it with the *first* part $(A_4)$ of the hetero-morphism morph$^4$.
   And additionally:
3. **Positioning, difference, matching conditions**
   3.1 The second part of the first morphism, its codomain or target, and the first part of the hetero-morphism, its domain, source, have to be matched.
   3.2 The first part of the second morphism, its domain or source, and the second part of the hetero-morphism, its codomain, target, have to be matched.

A hetero-morphism is the rejectional morphism of an acceptional morphism. But this distinction has first to be established. Without the distinction between acceptional and rejectional morphism, the constructed hetero-morphism is not yet placed. To realize its correct placement, a new condition has to be fulfilled. It is the role of the difference relations to organize such a placement of a not yet positioned hetero-morphism.

It seems that Toth’s approach is not considering this part of the construction.
Toth’s examples are showing a solution in the sense of scheme (a), i.e. a hetero-morphism (heter) is defined as a direct inversion of an acceptional morphism (morph). And morph is a composition of morph and morph.

**Example**

\[
\begin{align*}
A_3 &= [\alpha^* \beta^*, a] \rightarrow [id1, \beta] = B_3 \\
\downarrow \text{INV, Subst} \\
B_4 &= [\beta \alpha, \alpha^*] \leftarrow [id1, \beta^*] = A_4
\end{align*}
\]

\[
[[id1, \beta^*], [\beta \alpha, \alpha^*]] = \text{heter}_4
\]

\[
x
[[\alpha^* \beta^*, a], [id1, \beta]] = \text{morph}_3
\]

Toth’s examples are showing a solution in the sense of scheme (a), i.e. a hetero-morphism (heter) is defined as a direct inversion of an acceptional morphism (morph). And morph is a composition of morph and morph.

**Inversion (categorical dualisation)**

It seems that the first step of ‘chiastic exchange’ is included in the definition of the inversion operation.

**Example**

1. **Chiastic exchange ("external exchange")**

\[
A_3 = [\alpha^* \beta^*, a] \rightarrow [id1, \beta] = B_3
\]

\[
\text{INV}(A_3 \rightarrow B_3) = \text{INV}(B_3) \rightarrow \text{INV}(A_3).
\]

This is the ‘exchange’ (by INV – Rule II)

\[
= \text{INV}(A_3) \leftrightarrow \text{INV}(B_3)
\]

2. **Inversions ("internal exchange")**

\[
A_3 = [\alpha^* \beta^*, a] = ([\alpha^* \beta] \rightarrow a)
\]

\[
B_3 = [id1, \beta] = (id1 \rightarrow \beta)
\]

\[
\text{INV}(A_3) = \text{INV}([[\alpha^* \beta] \rightarrow a])
\]

\[
= (\text{INV}([\alpha]), \text{INV}([\alpha^* \beta])) : \text{INV – Rule II}
\]

\[
= ([\alpha^* \beta] \rightarrow [a\beta]) = A_4
\]

\[
\text{INV}(B_3) = \text{INV}(id1 \rightarrow \beta)
\]

\[
= (\text{INV}(\beta) \rightarrow \text{INV}(id1)) : \text{INV – Rule II}
\]

\[
= [\beta \rightarrow id1] = B_4
\]

Toth’s notation for brackets [x, y] in [x, y], [z] of a hetero-morphism could mislead to a wrong interpretation if taken as a mapping "(x) → (y), but [x, y] is by definition, in this setting, a non-decomposable "object".
Further comparisons: Are Diamanten diamonds?
Hence, the difference to my approach is clear. Hetero-morphisms are not directly accessible by exceptional morphisms but are depending on the structure of the composition of morphisms. That is, the process of composition is reflected in hetero-morphisms, while exceptional morphisms are the positive or direct results of compositions, i.e. $\text{morph}_1 \circ \text{morph}_2 = \text{morph}_3$.

A consequence of Toth’s approach seems to be the lack of jumping situation or saltisitions for general Diamanten. Toth’s hetero-morphisms are connected and composed without any gaps to be over-jumped and hence, the associativity rule holds unrestrictedly.

The main difficulty to understand properly Toth’s approach has two reasons:
1. the diagrams used are not always clear. Different readings are possible, because
2. there are no formal matching conditions (MC) for compositions of morphisms and hetero-morphisms defined.

![Diagram](Toth's_Semiotics.nb)
Again, because diagrams are not telling much without their formal definitions, I repeated the formal definitions of the diagrams for Diamanten and for diamonds.

And, unfortunately, programs are still not stable enough to produce proper results in different formats.

The above diagram is semiotically concretised by Toth’s example for a semiotic Diamant based on 3 composed semiotic morphisms.

As a first result we might observe that Toth’s hetero-morphisms are a kind of counter-morphisms. They might even have the properties of being: "... genuinely tetradic, chiastic, antidromic and 4-fold." And they are connected with morphisms by inversion and chiastic exchange. Obviously those properties are necessary but maybe not sufficient for diamonds.

What I proposed as diamonds at different places, are structures with very different laws compared to the laws of categories. That is, diamonds, which consist of a complementary interplay of categories and saltatories, are as categorical systems identitive, commutative and associative in respect to their objects, morphisms and composition. Therefore, inheriting all the laws and methods from category theory. In sharp contrast, saltatories as parts of diamonds, are ruled by difference, jumps (saltisitions) and jump-associativity, etc.

Additionally, diamonds as such, are containing bridges and bridging rules between categories and saltatories.
**Again, diamond definitions**

Diamond composition rule

\[(M_a \rightarrow O_{\omega}) \oplus (O_{\alpha} \rightarrow I_{\omega}), \]

\[O_{\omega} = \text{diff}(O_{\alpha}),\]

\[O_{\alpha} = \text{diff}(O_{\omega}).\]

---

Diagram of diamond composition

\[
\begin{array}{c}
(M_a \xrightarrow{\text{morph}} O_{\omega}) \oplus (O_{\alpha} \xrightarrow{\text{morph}} I_{\omega}) \\
\text{diff} / \text{diff} \\
\text{id} / \text{id} \\
(M_a \xrightarrow{\text{morph}_3} I_{\omega})
\end{array}
\]

Diagram of diamond composition with matching conditions MC

\[
\omega_i \in f, \quad a_2 \in g:
\delta(a_2) = \alpha_4 \cap \delta(\omega_i) = \omega_4 \Rightarrow \omega_4 \leftrightarrow \alpha_4,
\]

\[
\begin{array}{c}
\omega_4 \leftarrow \alpha_4 \\
\downarrow \\
\left[ \alpha_1 \rightarrow \omega_1 \cap \alpha_2 \rightarrow \omega_2 \right] \\
\downarrow \\
\alpha_3 \xrightarrow{f} \omega_3
\end{array}
\]

One of Toth’s semiotic motivations for diamonds

"Ein sowohl für die Semiotik wie für die Kybernetik wichtiges Ergebnis ist, dass zwar die Abbildung von Zeichenklassen auf Morphismen eindeutig ist, nicht aber die Abbildung von Morphismen auf Realitätsthematiken: Während also \(a^n \rightarrow (2.1), \text{id}2 \rightarrow (2.2), \beta \rightarrow (2.3)\) gilt, erhalten wir für \((2.1), (2.1), (2.2), (2.2), (2.2)\) und \((2.3), (2.3)\) jedesmal \text{id}2, d.h. bei den Semiosen zwischen Trichotomischen Triaden, die ja aus Realitätsthematiken konstruiert sind, können die für Zeichenklassen eingeführten Morphismen nicht zwischen den trichotomischen Stellenwerten unterscheiden!

Sollte diese Identifikation statthaft sein, kommt denjenigen Trichotomischen Triaden, die wie etwa die Nrn. 589 und 617 ausschliesslich aus semiotischen Heteromorphismen (und idx) und vor allem denjenigen, die (neben) idx nur Morphismen und ihre korrespondierenden Heteromorphismen enthalten wie etwa den Nrn. 551, 561 und 564, besondere Bedeutung im Zusammenhang mit einer erst zu entwickelnden kybernetischen Semiotik der 2. Ordnung bzw. einer Vereinigung von Semiotik und Polykontexturalitätstheorie zu." (Toth, Kybernetik, p.663/64)
Playing the game

Now I would like to test Toth’s construction rules (INV, exchange) in reconstructing his examples. It seems, that the INV rule is always working if applied in the introduced sense as “INV = inv(inv, inv)” . With the help of the exchange advise, INV is reduced to "(inv, inv)".

Again, Toth’s example and an explicite notation:

\[
\begin{align*}
\{\alpha, \alpha^{-1}\beta^{-1}\} & \leftarrow \{\beta, \text{id}_1\} : \text{morph}_4 \\
\beta \setminus \beta' \setminus \alpha \setminus \alpha^\beta \setminus \beta \setminus \text{id}_1 \setminus \text{id}_1 \setminus \beta \setminus \alpha \\setminus \beta' \setminus \text{id}_1 \\
\beta' \setminus \text{id}_1 \setminus \beta \setminus \alpha \\setminus \beta' \setminus \text{id}_1
\end{align*}
\]

explicit notation

\[
\begin{align*}
\{\alpha \leftarrow (\alpha^{-1}\beta^{-1})\} & \leftarrow \{\beta \leftarrow \text{id}_1\} : \text{morph}_4 \\
\beta' \setminus \text{id}_1 \setminus \alpha \setminus \alpha \setminus \beta \setminus \alpha \setminus \beta \setminus \text{id}_1 \\
\beta' \setminus \text{id}_1 \setminus \alpha \setminus \beta \\setminus \alpha \setminus \beta' \setminus \text{id}_1
\end{align*}
\]

- **Example 1**

\[
\begin{align*}
(1.3 \times 1.2 \times 3.1) & \\
[[\text{id}_1, \beta^\alpha], [\beta^\alpha, \alpha^\beta]] \\
[\alpha^\beta, \alpha^\beta, \alpha] & \circ [\text{id}_1, \beta] \\
[\alpha^\beta, \alpha] & \circ [\text{id}_1, \beta] \\
(3.1 \times 1.2 \times 1.3)
\end{align*}
\]
1. \( A_3 = [\alpha^\beta^\alpha, \alpha] \Rightarrow A_4 = [\beta\alpha, \alpha^\alpha] = [\beta\alpha \leftarrow \alpha^\alpha] \)
2. \( B_3 = [\text{id}_{1}, \beta] \Rightarrow B_4 = [\text{id}_{1}, \beta^\star] = [\text{id}_{1} \leftarrow \beta^\star] \)

**INVERSION INV**

**ad1.** \( \text{INV} ([\alpha^\beta^\alpha, \alpha]) = \text{INV} ([\text{INV} ([\alpha^\beta^\alpha]), \text{INV} ([\alpha])] \)
\( = [\text{INV} ([\alpha]), \text{INV} ([\alpha^\beta])]) \)
\( = [[\alpha^\star], [\beta\alpha]] = [\alpha^\star, \beta\alpha] = [\alpha^\star \leftarrow \beta\alpha] = A_4 \)

**ad2.** \( \text{INV} ([\text{id}_{1}, \beta]) = \text{INV} ([\text{INV} (\text{id}_{1}), \text{INV} (\beta)]) \)
\( = [\text{INV} (\beta), \text{INV} (\text{id}_{1})] \)
\( = [\beta^\star, \text{id}_{1}] = [\beta^\star \leftarrow \text{id}_{1}] = B_4 \)

**Example 2**

\[
\begin{align*}
(3.1 \times 2.1 \times 1.3) \\
[\beta^\star, \text{id}_{1}], [\alpha^\star, \beta\alpha] \\
[\alpha, \alpha^\star \beta^\alpha] \circ [\beta, \text{id}_{1}] \\
[\alpha, \alpha^\star \beta^\alpha], [\beta, \text{id}_{1}] \\
(1.3 \times 2.1 \times 3.1)
\end{align*}
\]

1. \( A_3 = [\alpha, \alpha^\star \beta^\alpha] \Rightarrow A_4 = [\alpha^\alpha, \beta\alpha] = [\alpha^\alpha \leftarrow \beta\alpha] \)
2. \( B_3 = [\beta, \text{id}_{1}] \Rightarrow B_4 = [\beta^\star, \text{id}_{1}] = [\beta^\star \leftarrow \text{id}_{1}] \)

**INVERSION INV**

**ad1.** \( \text{INV}[\alpha, \alpha^\star \beta^\alpha] = [\alpha^\star, \beta\alpha] \)
\( = \text{INV} ([\text{INV}[\alpha], \text{INV} [\alpha^\star \beta^\alpha]]) \)
\( = \text{INV}[\alpha^\star \beta^\alpha], \text{INV}[\alpha] \)
\( = [[\beta\alpha], \alpha^\star] = [\beta\alpha, \alpha^\star] = [\beta\alpha \leftarrow \alpha^\alpha] = A_4 \)

**ad2.** \( \text{INV}[\beta, \text{id}_{1}] = [\beta^\star, \text{id}_{1}] \)
\( = \text{INV} [\text{INV}(\beta) \rightarrow \text{INV}(\text{id}_{1})] \)
\( = [\text{INV}(\text{id}_{1}) \rightarrow \text{INV}(\beta)] \)
\( = [\text{id}_{1} \rightarrow \beta^\star] = B_4 \)

Are Toth’s hetero-morphism and semiotic diamonds the same constructs or constructs in the same spirit as the diamond categories introduced by my own intuitions? What could the difference be? And how could such a possible difference matter?

Toth’s construction is considering the complementarity between acceptional and rejectional morphisms based on inversion (INV) and chiasmic exchange.

This corresponds to some sketches I produced myself. But I conceived them as *abbreviations* of the difference based constructions.

“Compositions as well as sautistics (jump-operations) are ruled by identity and associativity laws. Complementarity between categories and saltatories, i.e., between acceptional and rejectional domains of diamonds, are ruled by difference operations.” (Kaeahr, p.3)
Comparision: Toth’s Diamanten and diamonds

The following definitions could give a hint to understand the difference between the two diamond constructions.

**Complementarity of Acc and Rej based on diff**

\[ X \in \text{Acc} \text{ iff compl}(X) \in \text{Rej} \]

1. \( X \in \text{Acc} \text{ if compl}(X) \in \text{Rej} \)
   \[
   \text{compl}(g \circ f) = \text{compl}(\text{compl}(g) \circ \text{compl}(f)) \\
   = \text{compl}(\text{diff}(\text{cod}(f)) \circ \text{diff}(\text{dom}(g))) \\
   = \text{compl}(B_{\text{cod}}^{-} \circ B_{\text{dom}}^{-}) = \omega_{4} \leftrightarrow a_{4}.
   \]
   
   (u: \omega_{4} \leftrightarrow a_{4}) \in \text{Rej}
   
   Hence, \((g \circ f) \in \text{Acc} \text{ if } (u: \omega_{4} \leftrightarrow a_{4}) \in \text{Rej} \)

2. \( X \in \text{Rej} \text{ if } X \in \text{Acc} \)
   \[
   \text{compl}(\omega_{4} \leftrightarrow a_{4}) = \text{compl}(\text{compl}(\omega_{4}) \leftrightarrow \text{compl}(a_{4})) \\
   = \text{compl}((A_{\text{dom}} \rightarrow B_{\text{cod}}) \circ (B_{\text{dom}} \rightarrow C_{\text{cod}})) \\
   = ((A_{\text{dom}} \rightarrow B_{\text{cod}}) \circ (B_{\text{dom}} \rightarrow C_{\text{cod}})) \\
   = (f \circ g).
   \]

3. Hence, \( X \in \text{Acc} \text{ iff compl}(X) \in \text{Rej} \).

In this "proof", the complementarity operation "compl" is used quite freely to do also the transitional job of completing the morphisms out of the objects. This is done by the operation of "difference" and "completition", which is completing domains and codomains to their morphisms. This points to the asymmetry of Acc- and Rej-domains.

Toth’s complementarity operation between acceptional and rejectional morphisms, played by INV and exchange, is symmetrical.

The open question for the construction of semiotic diamonds still is: How is the difference relation defined, concretely?

Again, Toth’s approach, despite its own merits, is not answering this questions, simply because they don’t exist for his Diamanten.

**Similarity?**

The nearest comparision between Toth’s approach to diamond and what I published myself can be found in the general complementarity between acceptional and rejectional morphisms as sketched below. Nevertheless, the definitions of the hetero-morphisms k, l, m are based on the abstractions of compositions and not on objects. That is, hetero-morphism \( k : \delta(a_{2}) = a_{4} \) and \( \delta(\omega_{1}) = \omega_{4} \). ETC!
\[ \omega_1 \in f, \; \alpha_2 \in g:\]
\[\delta(\alpha_2) = \delta(\omega_1) = \omega_4. \Rightarrow \omega_4 \leftrightarrow_k \alpha_4\]

Thus, the operation \(\text{reject}(gf)\) of the composition of the acceptance morphisms \(f\) and \(g\) is producing the \(\text{rejectance}\) hetero-morphism \(k\).

And the operation \(\text{accept}(k)\) of the rejectance morphism \(k\) is producing the \(\text{acceptance}\) of the composition of the morphisms \(g\) and \(f\).

**Comparision of Diamanten and diamonds**

Diamond MC
\[\alpha_1 \equiv \alpha_3 \equiv \alpha_7, \]
\[\alpha_2 \equiv \alpha_4 \equiv \alpha_6, \]
\[\alpha_5 \equiv \alpha_8 \equiv \alpha_9, \]
\[\omega_1 \equiv \omega_4 \equiv \omega_9, \]
\[\omega_2 \equiv \omega_3 \equiv \omega_8, \]
\[\omega_5 \equiv \omega_6 \equiv \omega_7.\]

Diamond MC plus MC for compositions

DiamantMC
\[\alpha_1 \equiv \alpha_3 \equiv \omega_4, \]
\[\omega_2 \equiv \omega_3 \equiv \omega_4.\]
That is,

$$\forall MC : \quad MC_{diamond} \neq MC_{Diamant} \implies \text{Diamanten} \neq \text{diamonds}$$

This detailed comparison of Toth’s semiotic diamonds (Diamanten) and the diamonds of diamond category theory has shown some results:

- Toth’s Diamanten are based on inversions of acceptional morphisms and are not constituting any rejectional morphisms.
- A proper definition of the matching conditions is missing.
- A comparison of the matching conditions for Diamanten and diamonds gives easy criteria for separation of both approaches.
- As a result, semiotic Diamanten are not working as semiotic models of categorical diamonds.
- Nevertheless, semiotic Diamanten are a novelty in semiotics and are opening up new fields of semiotic studies.
Sketch on semiotics in diamonds

Embedding semiotics into anchored diamonds

Rudolf Kaehr Dr.@
ThinkArt Lab Glasgow

Abstract
Semiotics are embedded into diamonds in a double way. Semiotics gets an internal environment as its neighbor semiotics and an external environment by its anchors. Embedding semiotics is a process of concretization of the abstract concept of Peircean semiotics.

1. Diamond embedments of semiotics

1.1. Semiotics within semiotics

Introduction of the semiotic scheme by Bense/Toth

\[ \text{ZR} = \left\{ \left[ a \right], \left( a \implies b \right), \left( a \implies b \implies c \right) \right\} \]

Firstness is a relation to itself, 'monadic relation': \( a \)
Secondness is a binary relation, 'dyadic relation': \( a \implies b \)
Thirdness is a ternary relation, 'triadic relation': \( a \implies b \implies c \)

An extensive study of a relational introduction of the Peircean semiotics is presented in [Toth, Einführung in die semiotische Relationentheorie]. Additionally, a further development to a ternary semiotics and its relation to Gunther's ternary epistemology is proposed.

1.1.1. Diamondization of semiotics

A diamondization of the semiotic scheme is naturally realized as a diamond interpretation of the semiotic relations, i.e. morphisms.

Firstness as a doublet
A composition always is accompanied by an environment of its morphisms. Therefore, an initial object or the number 1, firstness, is diamond theoretically always doubled: as itself and as its environment, i.e.( A | a). That is, as a morphism, and as a hetero-morphism. A diamond initial object is not a singular object but a doublet. Also called bi-object. Furthermore, self-identity is able to distinguish its directionality as left (lo) and right (ro) order.
\[
\mathrm{Diam}(\mathbb{Z}) = (A \mid a), (A \implies B \mid c), (A \implies B \implies C \mid b_2 \leftarrow b_1)
\]

**Peirce – Firstness** is a relation to itself: \(a \implies a\)

\[
\mathrm{Diam}(a \implies a) : \\
A \implies B \implies A : \text{cod}(f) = \text{dom}(g), \text{ hence } A = B \\
A \implies A \mid b_1 \leftarrow b_2 : A = B \\
A \implies A \mid a_1 \leftarrow a_2 : A = B \\
A \mid a \\
\text{Hence, } \text{diamond – firstness is } A \mid a.
\]

**right\mid left – circularity for monads** \(A \mid a\):

If \(A^a\) then \(a^0\), hence \(A^a \mid a^0\)

If \(A^a\) then \(a^0\), hence \(A^a \mid a^0\)

**Peirce – Secondness** is a binary relation: \(A \implies B\).

\[
\mathrm{Diam}(A \implies B) : \\
(A \implies B \implies A) \circ (B \implies A \implies B) \\
(A \implies A \mid b) \circ (B \implies B \mid a) \\
(A \mid b) \circ (B \mid a) \\
A \implies B \mid a \leftarrow b : a = b \\
A \implies B \mid c
\]

\text{Hence, } \text{diamond – secondness is } A \implies B \mid c.

**Alternative:**

1. \((A \implies B) \cdot (A \implies B \implies B) : \\
A \implies B \implies B \\
A \implies B \implies B \mid b_2 \leftarrow b_1 : b_2 = b_1 \\
A \implies B \mid c.
\]

2. \((A \implies B) \cdot (A \implies A \implies B) : \\
A \implies A \circ A \implies B \\
A \implies A \circ A \implies B \mid a_2 \leftarrow a_1 : a_2 = a_1 \\
A \implies B \mid c.
\]

**Peirce – Thirdness** is a ternary relation: \(A \implies B \implies C\).

\[
\mathrm{Diam}(A \implies B \implies C) : \\
A \implies B \implies C : \text{cod}(f) = \text{dom}(g), \\
A \implies C \mid c_1 \leftarrow b_2
\]
Classificatory remarks

In Transit (Toth, 2008)
http://www.uni-klu.ac.at/iff-tewi/inhalt/280.htm

For a start, it might be a significant result to proof the difference with the simple example of Toth's dually invariant sign class \((3.1.2.2.1.3) \times (3.1.2.2.1.3)\), which is, as it turns out, contexturally different, i.e. \((3.1.3, 2.2.12, 1.3) \neq (3.1.3, 2.2.12, 1.3)\).
This, obviously, is based on a different paradigm and its duality results for identity:

1.2. Diamond semiotic values

1.2.1. Semiotic values

Semiotic principle for sign classes according to Bense/Toth

1. Principle of Triadic Diversity:
The general sign class structure has the form \((a.b.c.d.e.f)\) with \(a, b, c, d, e, f \in \{1, 2, 3\}\) and \(a \neq b \neq c\).

2. Principle of Degenerative Triadic Order:
The general sign class structure must have the form \((3.a.2.b.1.c)\).
3. **Principle of Trichotomic Inclusion:**

(3.a 2.b 1.c) with \( a \leq b \leq c \) and \( a, b, c \in \{1, 2, 3\} \).

"However, we may question if the three semiotic restrictions do hold. From the standpoint of relational algebra, nothing speaks in favor of the Principle of Semiotic Inclusion." (Toth, Ghost, p. 10)

### 1.2.2. Mediation of semiotics

**Sem** 

\[ \text{meditation table MM (Kaehr, White Papers 1873)} \]

<table>
<thead>
<tr>

\text{Sem}^1 = \{1, 2, 3\} \\
\text{Sem}^2 = \{2, 3, 4\} \\
\text{Sem}^3 = \{1, 2, 4\} \\
\text{Sem}^4 = \{1, 3, 4\} 
\end{cases} \) |

\[ \text{Sem}^{(6,4)} = \begin{cases} 
1 \rightarrow 2 \rightarrow 3 \rightarrow x \\
x \rightarrow 2 \rightarrow 3 \rightarrow 4 \\
1 \rightarrow 2 \rightarrow x \rightarrow 4 \\
1 \rightarrow x \rightarrow 3 \rightarrow 4 
\end{cases} \]

\[ \prod \text{sem}^i, \ i = 1, 2, 3, 4 \]

Null
**Numeric binary matrix**

\[ \text{Sem}^{(k,1)} \times \text{Sem}^{(k,1)} = \]
\[
\begin{bmatrix}
\text{Sem}^1 \times \text{Sem}^1, & \text{Sem}^2 \times \text{Sem}^2, & \text{Sem}^3 \times \text{Sem}^3, & \text{Sem}^4 \times \text{Sem}^4
\end{bmatrix}:
\]

\[\text{Sem}^1 \times \text{Sem}^1 = \begin{pmatrix}
1 & 2.1, & 2.2, & 2.3, & 2.4 \\
2 & 1.1, & 1.2, & 1.3, & 1.4 \\
3 & 1.2, & 1.3, & 1.4, & 1.5 \\
4 & 1.3, & 1.4, & 1.5, & 1.6
\end{pmatrix}\]

\[\text{Sem}^2 \times \text{Sem}^2 = \begin{pmatrix}
1 & 2.1, & 2.2, & 2.3, & 2.4 \\
2 & 2.1, & 2.2, & 2.3, & 2.4 \\
3 & 2.1, & 2.2, & 2.3, & 2.4 \\
4 & 2.1, & 2.2, & 2.3, & 2.4
\end{pmatrix}\]

\[\text{Sem}^3 \times \text{Sem}^3 = \begin{pmatrix}
1 & 2.1, & 2.2, & 2.3, & 2.4 \\
2 & 2.1, & 2.2, & 2.3, & 2.4 \\
3 & 2.1, & 2.2, & 2.3, & 2.4 \\
4 & 2.1, & 2.2, & 2.3, & 2.4
\end{pmatrix}\]

\[\text{Sem}^4 \times \text{Sem}^4 = \begin{pmatrix}
1 & 2.1, & 2.2, & 2.3, & 2.4 \\
2 & 2.1, & 2.2, & 2.3, & 2.4 \\
3 & 2.1, & 2.2, & 2.3, & 2.4 \\
4 & 2.1, & 2.2, & 2.3, & 2.4
\end{pmatrix}\]

**4 – contextual semiotic matrix**

\[ \text{Sem}^{(k,2)} = \]
\[
\begin{pmatrix}
\text{MM} & 1 \quad 2 \quad 3 \quad 4
\end{pmatrix}
\]

**Semiotic reduction matrix:**

\[ \begin{pmatrix}
\text{MM} & 1 \quad 2 \quad 3 \quad 4
\end{pmatrix}
\]
1.2.3. Ternary semiotics as composed by binary relations

If unary triadic signs are defined as compositions of dyadic sub-signs then their compositions to binary and ternary triadic sign systems should have a natural decomposition into their sub-signs. A natural decomposition is guided mainly by its mathematical constructions and not by any content or other interest oriented restrictions to formal procedures. If a composition is a sign then all its permutation have to be accepted as signs.

\[
\text{Sem}^{(3;1)} = (\text{Sem}^1, \text{Sem}^2, \text{Sem}^3) = \{1_{1,3}, 2_{2,1}, 3_{2,3}\}
\]

\[
\text{Sem}^{(3;1)} \times \text{Sem}^{(3;1)} =
\begin{bmatrix}
(\text{Sem}^1 \times \text{Sem}^1), (\text{Sem}^2 \times \text{Sem}^2), (\text{Sem}^3 \times \text{Sem}^3)
\end{bmatrix}
\]

\[
\begin{align*}
(\text{Sem}^1 \times \text{Sem}^1) &= (1, 2) \times (1, 2), \\
(\text{Sem}^2 \times \text{Sem}^2) &= (2, 3) \times (2, 3), \\
(\text{Sem}^3 \times \text{Sem}^3) &= (1, 3) \times (1, 3)
\end{align*}
\]
1.2.4. Semiotic vs. polysemiotic sign classes

**Sign classes**

\[
\begin{align*}
[3.1 & 2.1 & 1.1] \\ 
\Rightarrow & [3.1, 2.1, 1.1, 3] = ([3.1, xx, 1.1, 3], [xx, 2.1, 1.1]) \\
\Rightarrow & (3.1, 2.1, 1.2) = ([3.1, xx, xx], [xx, 2.1, 1.2])
\end{align*}
\]

**Toth's non-sign classes**

\[
\begin{align*}
[3.1 & 3.2 & 1.3] \\ 
\Rightarrow & ([3.1, xx, 1.3, 3], [xx, 3.2, xx]) \\
\Rightarrow & [2.1, 2.2, 1.2] = ([2.1, xx, 2.2, xx], [xx, 2.2, xx]) = ([2.1, 2.2, 1.2]) \\
\Rightarrow & [1.1, 1.3, 3.1] = ([1.1, xx, xx], [1.1, 1.3, 3.1]) = ([1.1, 1.3, 3.1])
\end{align*}
\]

Null
1.2.5. A special case, (3.1.2.31.3)?

Toth mentions a special case in his new classification of sign classes: (3.1 2.2 1.3) x (3.1 2.2 1.3), which is "the dual invariant sign class". (Toth, Ghost, p. 14)

A polycontextural micro-analysis of the duality shows a subtle difference which is not confirming in detail the "dual invariance" of Toth’s mathematical semiotic approach to sign classes.

1. For (3.1.2.1.3) x (3.1.2.1.3) = (3.1.3, 2.2 1.2, 1.3)  
   x (3.1.3, 2.2 1.2, 1.3) = (3.1.3, 2.1 1.1, 1.3)  
   x (3.1.3, 2.1 1.1, 1.3) = (3.1.3, 2.1 1.1, 1.3)  

   (3.1.2.1.3) x (3.1.2.1.3) = (3.1.3, 2.1 1.1, 1.3)  
   (3.1.2.1.3) x (3.1.2.1.3) = (3.1.3, 2.1 1.1, 1.3)  
   (3.1.2.1.3) x (3.1.2.1.3) = (3.1.3, 2.1 1.1, 1.3)  

   Hence, (3.1.2.1.3) ≠ (3.1.2.1.3) in the contextual setting.

The special case of a dual invariance, (3.1 2.1 1.3) x (3.1 2.2 1.3), doesn’t hold in a polycontextural setting because the decomposition shows the inverse order of (2.2, 1.2) in the dual case, i.e., (2.2, 1.2) ≠ (2.2, 1.2).
Category representation of the mathematical and the polycontextual approach for $\text{Sem}^{(3)}$.

\[
\begin{array}{ccc}
1 & 2 & 3 \\
1 & \text{id}_1 & \alpha & \beta \alpha \\
2 & \alpha^* & \text{id}_2 & \beta \\
3 & \beta^* & \alpha^* & \text{id}_3 \\
\end{array}
\quad \text{versus} \quad
\begin{array}{ccc}
1 & 2 & 3 \\
1 & \text{id}_1 & \alpha_1 & \alpha_3 \\
2 & \alpha_1' & \text{id}_2 & \alpha_2 \\
3 & \alpha_3' & \alpha_2' & \text{id}_{2,3} \\
\end{array}
\]

1. Categorical:
\[
\{3, 1, 2, 1, 3\} \rightarrow (\beta^* \alpha^*, \text{id}_2, \beta \alpha) \Rightarrow \chi(3, 1, 2, 1, 3) = (\beta^* \alpha^*, \text{id}_2, \beta \alpha).
\]
hence $\chi(3, 1, 2, 1, 3) = x(3, 1, 2, 1, 3)$.

2. Contextual:
\[
\{3, 1, 5, 2, 2, 1, 2, 1, 3\} = (\alpha^*, \text{id}_2, \alpha_3) \Rightarrow
\]
x(3, 1, 5, 2, 2, 1, 2, 1, 3) = (\alpha^*, \text{id}_2, \alpha_3)

Hence, $\chi(3, 1, 2, 2, 1, 2, 1, 3, 1, 3) \neq \chi(3, 1, 2, 2, 1, 2, 1, 3, 1, 3)$, esp.
x(1, 2, 2) = \text{id}_2 and x(1, 2, 2) \neq \text{id}_2.

**Polylogical negation example**

Similar situation for $m$-valued and $m$-contextual logics.

$m = 3$:

**logical negation**: $p = \{1, 2, 3\}$, non$_1 p = \{2, 1, 3\}$, hence non$_1 (3) = 3$.

**contextual negation**: $p = \langle T_{2,3}, F_{1,2}, F_{2,3}, F_{3,2} \rangle$, non$_1 p = \langle F_{1,2}, T_{2,3}, F_{3,2} \rangle$,

hence non$_1 (F_{3,2}) = F_{2,3}$ and $F_{2,3} \neq F_{3,2}$.

**Duality and identity for $\text{Sem}^{(3,1)}$**

dual $(\text{id}_1, \text{id}_2, \text{id}_3) = (\text{id}_1, \text{id}_2, \text{id}_3)$ for Bense - Semiotics, i.e.

dual $(\text{id}_i) = \text{id}_i$, $i = 1, 2, 3$

dual for $\text{Sem}^{(3,1)}$

dual $(\text{id}_1, \text{id}_2, \text{id}_3) = (\text{id}_1, \text{id}_2, \text{id}_3)$

dual $(\text{id}_1, \text{id}_2, \text{id}_3) = (\text{id}_3, \text{id}_3, \text{id}_3)$

**Non-Peirce-Bensean self-dual sign classes**

**Duality, identity and reflectionality**

**1.2.6. Diamond semiotics abstract scheme**

\[
\text{Diamond}_{\text{Sem}}^{(3,1)} =
\begin{array}{ccc}
\{1, 1\} \rightarrow \{1, 2\} \rightarrow \{1, 3\} \\
\downarrow & \downarrow & \downarrow \\
\{2, 1\} \rightarrow \{2, 2\} \rightarrow \{2, 3\} \\
\downarrow & \downarrow & \downarrow \\
\{3, 1\} \rightarrow \{3, 2\} \rightarrow \{3, 3\} \\
\end{array}
\]

This kind of presentation (cf. Toth, Ghost, p. 13) is intended to give an idea of the embeddement of semiotics and its diamond environments as a further 'external' embeddement of semiotics. Hence,
Semiotics in polycontextural diamond constellations are twofold embedded. 1. by their neighbor-semiotics and 2. by their diamond environments. Obviously, semiotics and diamond environments are equiprimordial (gleichursprünghlich). In a further step of concretization, the construction gets its localization as a 3. embedded demand by its place-designators of the kenomic anchors.

1.3. Diamond semiotic interpretations of \((M, O, I)\)

1.3.1. Semiotic interpretation

Independent of the reasonability of the decision to introduce meaningful interpretations to the numeric classification of sign and sub-signs into object, \(O\), medium, \(M\), and interpretation, \(I\), with its differentiations into sub-distinctions, the distinctions are made in the mode of *is-abstractions*. That is, the decision to interpret, e.g., 2.1 as \(M(I) = \text{sin-sign}\), is definitive and identical in all possible semiotic contexts. No sin-sign can change in its use to a legi-sign or to a symbol. This fact is further proof of its identity heritage from classical ontology and logic. Possibilities of thematizations are augmented in the case of embedded semiotics.

\[
\begin{align*}
\text{Semiotics} \\
ZR^{[3,1]} &= R(M, I, O) \\
M &= M(O), \ M(I), \ M(M) \\
M &= \{\text{quali-sign}, \ \text{sin-sign}, \ \text{legi-sign}\}, \\
O &= O(O), \ O(I), \ O(M) \\
O &= \{\text{icon, index, symbol}\}, \\
I &= I(O), \ I(I), \ I(M) \\
I &= \{\text{themis, dicent, argument}\}.
\end{align*}
\]

1.3.2. Polysemiotic interpretations

\[
\text{Semiotic interpretation: } \text{Sem}^{[4,1]}(M, I, O) = \begin{bmatrix}
M_{1,3} & I_{1,3} / M_2 \\
O_{2,3} & I_{2,4} / O_1
\end{bmatrix}
\]
1.3.3. Diamond semiotic interpretations

\[ \mathbb{ZP}^{[4]} = \mathbb{R} \left[ \left\{ \mathcal{M}_{1,2,3,4}, \mathcal{I}_{1,2,3,4}, \mathcal{O}_{1,2,3,4} \right\} \right] \]

\[ \mathcal{M}^{[4]} : \]
\[ M(1) = M(M_1), M(I_1), M(O_1), x \]
\[ M(2) = x , M(M_2), M(I_2), M(O_2) \]
\[ M(3) = M(M_3), M(I_3), x , M(O_3) \]
\[ M(4) = M(M_4), x , M(I_4), M(O_4) \]

\[ \mathcal{O}^{[4]} : \]
\[ O(1) = O(M_1), O(I_1), O(O_1), x \]
\[ O(2) = x , O(M_2), O(I_2), O(O_2) \]
\[ O(3) = O(M_3), O(I_3), x , O(O_3) \]
\[ O(4) = O(M_4), x , O(I_4), O(O_4) \]

\[ \mathcal{I}^{[4]} : \]
\[ I(1) = I(M_1), I(I_1), I(O_1), x \]
\[ I(2) = x , I(M_2), I(I_2), I(O_2) \]
\[ I(3) = I(M_3), I(I_3), x , I(O_2) \]
\[ I(4) = I(M_4), x , I(I_4), I(O_4) \]

1.3.3. Diamond semiotic interpretations

\[ \text{Sem}_{\text{diamond}}^{[4]}(M, I, O) = \left[ \begin{array}{cc}
M_{1,2,3,4} & I_{1,2,3,4} \\
O_{2,3,4} & O_{1,2,3,4}
\end{array} \right] \left[ \begin{array}{c}
\left\{ \mathcal{M}_{1,2,3,4}, \mathcal{I}_{1,2,3,4}, \mathcal{O}_{1,2,3,4} \right\} \end{array} \right] \]

2. Anchored diamonds

2.1. Anchored semiotics

Semiotics are conceived by Bense/Toth as anchor-free.\(^7\)
2.2. Anchored diamonds

\[
\begin{align*}
\text{sign} & : [1, 2, 3] \\
\phi & : \langle \phi, \phi \rangle \\
\langle 1, \phi \rangle & : \langle 1, 1 \rangle
\end{align*}
\]

2.3. Dissemination of diamonds

2.3.1. Disseminated semiotics

Diamond - Semiotics $DS^{(1, 1)}$

\[
\begin{align*}
I. & : A \mid a \\
II. & : A \rightarrow B \mid b \\
III. & : A \rightarrow C \mid b_1 \rightarrow b_2 \\
IV. & : A \rightarrow D \mid b_1 \leftrightarrow b_3 \mid c_1 \leftrightarrow c_2 \\
0. & : \phi \mid \phi
\end{align*}
\]

\[
\text{Diss}^{(n, 1)}(DS^{(1, 1)}) = \begin{pmatrix}
DS^{(1, 1)} & DS^{(2, 1)} & \cdots & DS^{(n, 1)} \\
DS^{(1, 2)} & DS^{(2, 2)} & \cdots & DS^{(n, 2)} \\
\cdots & \cdots & \cdots & \cdots \\
DS^{(1, n)} & DS^{(2, n)} & \cdots & DS^{(n, n)}
\end{pmatrix}
\]

2.3.2. Disseminated diamonds

\[
\text{Diss}^{(n, n)}(\text{Diam}^{(1, 1)}) = \begin{pmatrix}
DS^{(2, 1)} & DS^{(2, 1)} & \cdots & DS^{(n, 1)} \\
\cdots & \cdots & \cdots & \cdots \\
DS^{(1, n)} & DS^{(2, n)} & \cdots & DS^{(n, n)}
\end{pmatrix}
\]

Notes

1 Comments

Peirce triads or trichotomies is based on his metaphysical intuition, nurtured by his studies of Kant and Hegel, and is not a product of a general generation scheme with steps from 1 to 3. Such a general generation scheme wouldn’t have a built-in stop function, it could go on to arbitrary magnitudes. Only a reconstructive interest allows to start with 1 and end with 3.

“Creation thus means ‘that Firstness (repertory of ‘possible’ cases) must be given, so that Secondness (the ‘real’ case) in the sense of singular, concrete and innovative givenness is selectable in dependency of also given Thirdness (determining law or necessity)’” (Bense and Walther 1973, p. 127).” (Toth, In Transit, p. 49)

From the point of view of the primary trichotomic intuition and its realization, monadic and
**Semiotics in diamonds.nb**

**1** Dyadic relations occur as reductions of the trichotomic intuition and its realization as a triadic relation. In this diamond theoretical and polycontextural approach to an embedding of semiotics, nothing is given. The givenness of the semiotic categories, firstness, secondness and thirdness, are a result of a speculative decision for a trichotomic paradigm of thinking and corresponding world model, initiated scientifically by Peirce.

**2** Classificatory remarks

As a first result, I would like to point to the scenario, which could be misunderstood. To construct an embedding of semiotics into diamonds doesn't establish a priority of semiotics over diamonds. Diamond of diamond theory, like diamond semiotics, are not results of trichotomic semiotics, neither of their application. As much as diamond category theory is not part of classical category theory (in all its forms), diamond semiotics is not part of semiotics (and all its forms, say, with retro-semiosis). The same pattern holds for the topics like "Lambda Calculi in polycontextural situations".

The reason is simple. Neither for category theory nor for (mathematical) semiotics (Toth), an interplay between categories and saltatories, categorical composition and saltatorial saltisition (jump-operation), exists. Hence, a reconstruction of diamonds in the framework of semiotics or category theory is, albeit its reductive results, missing the point.

Hence, semiotics (and categories) are defined by objects, morphisms and composition of morphism, and are not including the concepts of separation, hetero-morphism, saltisition and bi-objects and their specific rules.

Neither co-algebras, co-categories or n-categories nor retro-semiosis and similar can be considered as proper concepts and methods for concretizations and realizations in diamond studies.

Again, nevertheless, it might produce interesting results in applying such concepts for reasons of modeling and simulation in contrast to realization.

On the other hand, there is no reason too, to restrict sign theory to the paradigm of Peircean semiotics (as it is represented by the Stuttgarter School). The same holds for category theory. Hence, the term semiotics might be properly used in constellation with diamond theory, polycontexturality and kenogrammatics.

**3** In Transit (Toth, 2008)

Interestingly, there is a highly sophisticated study accessible by Toth which is on the way to abolish, step by step, the arbitrary (and ideological) restrictions to semiotics as they had been superimposed by Bense for interpretational reasons and in disharmony with the formal possibility of semiotics as such.

Personally, I just got access to In Transit and other free downloadable e-books from UNI Klagenfurt| Reihe KBT: [http://www.uni-klu.ac.at/iff-tewi/inhalt/280.htm](http://www.uni-klu.ac.at/iff-tewi/inhalt/280.htm)

It is therefore not yet the place to go into more details to compare mathematical and polycontextural diamond semiotics more properly.

Albeit the fact that Gotthard Gunther fully accepted my approach of a dissemination of formal systems as an approach to formalize his polycontextural logic, similar philosophical and anti-formalistic restrictions had been superimposed by Gunther and his followers.

**4** Non-Peirce-Bensean self-dual sign classes

Additionally to the special self-dual sign class "(3.1 2.2 1.3)" of the 10 accepted sign classes, all other self-dual sign classes, not included in the Peirce-Bensean semiotics, should be accepted. Hence the sign sets, (3.2 2.2 2.3) as a general sign class/set and (2.1 2.2 1.2) as a non-sign class, or (1.2 1.1 1.2) too, are self-dual and structurally, in general, not different from the special case "(3.1 2.2 1.3)" of the privileged 10 sign classes.

In general, all self-dual sign sets (x.y id y.x), i=1,2,3 seems to be special sign classes.

A main argument against restrictions in the definition of sign classes might be the fact that accepted operations on signs are able to transform accepted sign classes into non-accepted sign class, then called sign sets.

**5** Duality, identity and reflectionality

As long as identity relations in formal systems aren't involved into reflectional interactions, the whole system remains classical.

Hence, semiotics of whatever formation, which aren't deconstructing their identity relation have to be classified as classical. Therefore, Toth's transclassical approaches to semiotics are doomed to fail their intentions to overcome classical restrictions.

Reflectionality of identity is possible only if the thematized identity is embedded in a polycontextural
environment with neighboring identity systems from whom it can be differentiated. Identity in classical systems is neighbor-less and hence not able to reflect itself.

7 Anchors

This free-floating illusion of anchor-free semiotics gets a concretization in the anchor-concept as it is constitutive by definition for diamonds. Anchors are realized in a kenomic grid. This happens at first as a proto-numbering of anchors. Anchors of diamonds, and as a consequence of semiotics too, are not part of diamonds or semiotics. That is, anchors are not represented by diamond’s firstness, secondness, thirdness and fourthness. Because anchors are realized in a kenomic grid, there numeric representation level shall be 0, hence Zeroness, also understood as Emptiness or Voidness. It presents the fifth category of anchored diamonds.

Toth introduced zeroness in his new design of transclassical semiotics. A comparision of both approaches is forthcoming.
Abstract

Some further thematizations and formalizations of diamond topics, especially triads, are presented. Triads, and founded triads, are presented in the context of Gunther’s epistemology, Toth’s semiotics with the help of Robertson’s “Algebra for triadic relations”. It is proposed that until now founding relations had been thematized externally only. An implementation of founding strategies into the system to be founded by the diamond approach is realizing the simultaneity of construction (model) and verification (foundation) of the triad. This approach is open for arbitrary n-ads.

1. Beyond binary relations?

1.1. Triads, trilogs, triplets

Representamen
"My definition of a representamen is as follows:
A REPRESENTAMEN is a subject of a triadic relation TO a second, called its OBJECT, FOR a third, called its INTERPRETANT, this triadic relation being such that the REPRESENTAMEN determines its interpretant to stand in the same triadic relation to the same object for some interpretant.” (Peirce)

Further Towards a Triadic Calculus
Christofer R. Longyear's reconstruction of Warren McCullochs hobbyhorse with Peircean triads.

Part 1-3:
http://www.vordenker.de/ggphilosophy/longyear-part_1.pdf

Triplets
<rdf:RDF
xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#"
xmlns:terms="http://purl.org/dc/terms/">
  <rdf:Description rdf:about="urn:x-states:New%20York">
    <terms:alternative>NY</terms:alternative>
  </rdf:Description>
</rdf:RDF>

Trilog
"Unary relations are obviously insufficient and quadratic (4airy) relations provide only minimally more capacity than triadic relations. Hence the choice is between two and three. Tarski studied binary relations extensively, but relation names played a
significant, distinct metadata role. Binary relations are sufficient to represent information in a fixed schema, but the names of these relations are inaccessible from the relation contents. Both a benefit and a disadvantage of binary relations is that they are inherently closed in an algebra of unary and binary operators."

"Trilog is of course equivalent to the use of a fragment of first order logic to define ternary predicates, a fragment which has less convenient syntax and safety rules."

Edward L. Robertson, An Algebra for Triadic Relations, 2005
http://www.cs.indiana.edu/~edrbtsn/

1.2. Morphisms as triads

1.2.1. Category theory

**Binary:**
morph = f(A, B), morph f: A --> B
morph: A â’ B
composition: (fg): A â’ B o B â’ C ==> A â’ C

**Ternary:**
morph = (A, f, B), (A, f, B) â’ Morph

\[
morph: \begin{pmatrix} f \\ \small{\downarrow} \\ \small{\rightarrow} \\ A \rightarrow B \end{pmatrix}
\]

Composition: \((fg)\):
\[
\begin{pmatrix} f \\ \small{\downarrow} \\ \small{\rightarrow} \\ A \rightarrow B \end{pmatrix} \circ \begin{pmatrix} g \\ \small{\downarrow} \\ \small{\rightarrow} \\ B \rightarrow C \end{pmatrix} = \begin{pmatrix} f \circ g \\ \small{\downarrow} \\ \small{\rightarrow} \\ A \rightarrow C \end{pmatrix}
\]

1.2.2. Semiotic foundation relation

Toth: "4. Starting with the geometric model of a sign class or reality thematic as an (equilateral) triangle, we notice that the semiotic foundational relations (FR) are orthogonal relations between the categories and the sign relations:

FR\(_1\) := I <--> (M --> O) \equiv (.3.) <--> ((.1.) --> (.2.))
FR\(_2\) := M <--> (O --> I) \equiv (.1.) <--> ((.2.) --> (.3.))
FR\(_3\) := O <--> (M --> I) \equiv (.2.) <--> ((.1.) --> (.3.))

where \(X, Y, Z \in \{.1., .2., .3.\}\) and \(X, Y, Z\) are pairwise different, which means that for \(Z\) any of the three prime-signs can be chosen, so that for FR\(_1\) the following 6 relations are possible:
2. Diamond triads

2.1. Robertson’s Trilogo

[Obviously, the following presentation is not more than a wee hint to a promising direction. Especially, there is no need to over-interpret the triadicity of the triadic approach(es). All the restrictions here to triadicity are for ‘didactical’ reasons only.]

Lower case letters (a, b, c, ..., x, y, z) are used as variables over D. The basic structures are sets of triples over D. We refer to these as triadic relations. Triangular form of notation: \((x, y, z) =: \frac{y}{x}z\) or \(\langle x, y, z \rangle\)

"...the triple \((x, l, z)\) indicates that the binary \(l(x, z)\) relationship holds."

3.1 Definition:
Let R, S, and T be triadic relations. The triadic join of R, S, and T, is defined

\[\text{trijoin}(R, S, T) \overset{\text{def}}{=} \left\{ \begin{array}{l} b \in D \\ a \in R \\ c \in T \\ x \in S \\ y \in R \\ z \in T \end{array} \right\} \]

An equivalent diagrammatic notation for \(\text{trijoin}(R, S, T)\) is \(\frac{S}{R T}\).

3.2 Definition:
\(I(R) \overset{\text{def}}{=} \left\{ x \right\} \) \(x\) occurs in the active domain of \(R\)

\(D^3(R) \overset{\text{def}}{=} \left\{ x, y, z \right\} \) \(x, y, \) and \(z\) occur in the active domain of \(R\)

\[\text{Trans}(B) \overset{\text{def}}{=} \frac{B}{B} = \frac{B}{B} \]

\[\rightarrow \]

\[\rightarrow \]

\[\rightarrow \]
2.2. Triadic diamonds

Lower case letters (a, b, c, ..., x, y, z) are used as variables over D. Lower case letters (\(\overline{a}, \overline{b}, \overline{c}, ..., \overline{x}, \overline{y}, \overline{z}\)) are used as variables over \(\overline{D}\).

The basic structures are bi-sets of diamond-triples over \((D, \overline{D})\).

We refer to these as triadic diamond relations.

Acceptional triadic relations are called \(R, S, T\).

The complementary rejectional dyadic relations are called \(r, s, t\).

Note:

The triadic rejectional relations \((r, s, t)\) occur as complementary relations to ternary acceptional relations \((R, S, T)\). Complementarity in diamond theory is based on an abstraction of the compositions of morphisms and is not to confuse with a categorical dualization of morphisms. Complementarily, categorical composition of morphism is possible only iff the criteria of saltatorial saltisition is realized.

This is not in conflict with the fact that category theory exists easily without any saltatory theory. Simply because saltatorial conditions of categories are implicitly used in the presuppositions and not yet set from the 'mind to the blackboard' (B. Brecht).

\[ \text{trijoin}_{\text{diam}}([R, r], [S, s], [T, t]) \text{ def } = \]

\[ \left\{ \left( \begin{array}{c} b \\ a \\ c \end{array} \right) : \exists x, y, z \right\} e \in [R, r] \& & \left\{ \left( \begin{array}{c} b \\ a \\ c \end{array} \right) : \exists x, y, z \right\} e \in [S, s] \& & \left\{ \left( \begin{array}{c} b \\ a \\ c \end{array} \right) : \exists x, y, z \right\} e \in [T, t] \right\} \]

An equivalent diamond diagrammatic notation for

\[ \text{trijoin}_{\text{diam}}([R, r], [S, s], [T, t]) = \left( \begin{array}{c} S \\ T \end{array} \right) \text{ with distributivity } : \left( \begin{array}{c} S \\ R \end{array} \right) \& & \left( \begin{array}{c} S \\ T \end{array} \right) \]

hence

\[ \text{trijoin}_{\text{diam}}([R, r], [S, s], [T, t]) = \text{trijoin}_{\text{diam}}\left( \left( \begin{array}{c} S \\ R \end{array} \right) \& & \left( \begin{array}{c} S \\ T \end{array} \right) \right) \]

\[ \text{trijoin}_{\text{diam}}\left( \left( \begin{array}{c} S \\ R \end{array} \right) \& & \left( \begin{array}{c} S \\ T \end{array} \right) \right) = \]

\[ \left\{ \left( \begin{array}{c} b \\ a \\ c \end{array} : \exists x, y, z \right) ; \left\{ \left( \begin{array}{c} b \\ a \\ c \end{array} : \exists x, y, z \right) ; \left\{ \left( \begin{array}{c} b \\ a \\ c \end{array} : \exists x, y, z \right) \right\} \right\} \]
2.2.1. Diamond triad rotation

Diamond triad rotation

\[
\begin{align*}
\text{tri} \text{join}_{\text{trim}}(S^R T) \parallel (S^T r t) = \\
\begin{bmatrix}
    b \\
    a \\
    c
\end{bmatrix} \in R \\
\begin{bmatrix}
    x \\
    y \\
    z
\end{bmatrix} \in S \\
\begin{bmatrix}
    y \\
    z \\
    c
\end{bmatrix} \in T
\end{align*}
\]

\[
\begin{align*}
\text{tri} \text{join}_{\text{trim}}(S^R T) \parallel (S^T r t) = \\
\begin{bmatrix}
    b \\
    a \\

\end{bmatrix} \in T
\end{align*}
\]

2.2.2. From triads to n-ads

2.3. Founded triads modeled by triadic diamonds

2.3.1. Definition of founded triads

Founding relations of \((S^4, S^6, \emptyset)\)

\[
\begin{array}{c}
\text{\emph{Founding relations of \((S^4, S^6, \emptyset)\)}} \\
\hline
S^4 \leftrightarrow S^6 \\
\end{array}
\]

Founding relations consists of a relation, \(r^E\), between monadic instances, \(S^4, S^6, \emptyset\) and dyadic relations, \((O \rightarrow S^4)\), \((S^6 \leftrightarrow S^0)\) and \((S^4 \rightarrow O)\).

Table of founding relations

\[
\begin{array}{c|c|c|c}
S^4 r^E (O \rightarrow S^0) & O r^E (S^6 \leftrightarrow S^0) & S^6 r^E (S^4 \rightarrow O) \\
\hline
\begin{array}{c|c|c|c}
\square & S^4 & \square \\
\square & \rightarrow & S^0 \\
\square & \downarrow & S^0 \\
\end{array} & \begin{array}{c|c|c|c}
\square & \emptyset & \square \\
\square & \rightarrow & S^0 \\
\square & \downarrow & S^0 \\
\end{array} & \begin{array}{c|c|c|c}
\square & S^6 & \square \\
\square & \rightarrow & S^0 \\
\square & \downarrow & S^0 \\
\end{array}
\end{array}
\]
Context — valued logic modeling of the founding relation

The unary founding relations \( r_0^f \) are modeled into a contextualized (parametrized) binary function:

\[
\begin{align*}
    f_{\text{binary}}^f &: (S^S, S^S, O) \times (S^S, S^S, O) \rightarrow \bigg( S^S; (S^S, S^S, O) \bigg) \\
    f_{\text{binary}}^f &: (S^S, S^S, O) \times (S^S, S^S, O) \rightarrow \bigg( S^S; (S^S, S^S, O) \bigg) \\
    f_{\text{binary}}^f &: (S^S, S^S, O) \times (S^S, S^S, O) \rightarrow \bigg( O; (S^S, S^S, O) \bigg)
\end{align*}
\]

In a ternary functional setting, binary operations, additional to the unary, are easily introduced.

Founding relation in 'trijoin'

**Founding relation in epistemic trilog**

\[
    r^f = \text{trijoin}_{\text{epistem}}(R, S, T) \iff \\
    \left\{ \begin{array}{l}
    S^0 \\
    \exists x, y, z \left[ \begin{array}{l}
    S^x z / (x) \in R \\
    S^y / (y) \in S \\
    \wedge \vee \in T
    \end{array} \right]
    \end{array} \right.
\]

Dyadic diamond foundations of triads

\[
\begin{array}{c|c|c}
    \text{triangular} & S^S r^f (O \rightarrow S^S) & \left\{ \begin{array}{l}
\end{array} \right. \\
    S^0 & S^S & \left\{ \begin{array}{l}
\end{array} \right. \\
    \text{Or} r^f (S^S \leftrightarrow S^S) & S^S & \left\{ \begin{array}{l}
\end{array} \right. \\
    \hline
\end{array}
\]

Monadic diamond foundations of triads

\[
\begin{array}{c|c|c}
    \text{triangular} & S^S r^f (O \rightarrow S^S) & \left\{ \begin{array}{l}
\end{array} \right. \\
    S^S & S^S & \left\{ \begin{array}{l}
\end{array} \right. \\
    \text{Or} r^f (S^S \leftrightarrow S^S) & S^S & \left\{ \begin{array}{l}
\end{array} \right. \\
    \hline
\end{array}
\]

**2.3.2. Composition of epistemic triads**

\[
    \text{trijoin}_{\text{epistem}}(R, S, T) \iff \left\{ \begin{array}{l}
    \exists x, y, z \left[ \begin{array}{l}
    x \in R \\
    S^x z / (x) \in S \\
    \wedge \vee \in T
    \end{array} \right]
    \end{array} \right.
\]

\[
\begin{array}{c|c|c}
    \text{triangular} & S^S & \left\{ \begin{array}{l}
\end{array} \right. \\
    S^0 & S^S & \left\{ \begin{array}{l}
\end{array} \right. \\
    \text{Or} & S^S & \left\{ \begin{array}{l}
\end{array} \right. \\
    \hline
\end{array}
\]
2.3.3. Composition of founded epistemic triads
Monadic foundations of epistemic triads

\[

\]
3. Gunther’s founding relation

3.1. The idea of founding relations

Diamonds might be considered as implementations of Gunther’s founding relation for reflectional triads. In other words, Gunther’s founding relation might get a formalization as a special triadic diamond in general diamond theory.

Triads, like \((sS, oS, oO)\), introduced by Gunther as the framework of a new epistemological paradigm, are reflected from each knot of the graph: \(sS(oS, oO)\), \(oS(sS, oO)\) and \(oO(sS, oS)\). Those relations are interpretations, respectively foundations of the triad as a whole from each of its monadic instances. Hence there are two modelings of reflection mapped into one triad: the triad and its foundations.
The foundations, realized from each standpoint of the triad, are delivering the 3 dyadic relations which are constituting the whole. Those parts, the dyadic relations, might be mirrored “outside” the whole as constitutive parts. Hence, the whole is a triad mirrored, inside-out, by its constitutive simultaneous dyads. Furthermore, the dyads of the triad are obtained from the unary elements, hence from monads. The whole construction for triadic reflectionality entails self-reflectionally a triad, consisting of a triad, 3 dyads and 3 monads.

"an exchange relation between logical positions
an ordered relation between logical positions
a founding relation which holds between the member of a relation and a relation itself."

TRIAD =(triad, dyad, monad).

But the wording of the construction suggests a simultaneity of the reflectional triad and its foundation by the founding relations of the triadic relation. That is, Gunther’s trans-classical model of subjectivity is developed in three steps:
1. The stipulation of the triadic model as such,
2. The analysis of the triad by the new idea of founding relations and
3. The composition of the specific founding relations together to the founded triadic model.

This might be interpreted as a diamond construction with:

\[
\begin{align*}
(\text{oO}) &= > (\text{sS}, \text{oS}, \text{oO}) || (\text{oS}, \text{sS}) \\
(\text{sS}) &= > (\text{sS}, \text{oS}, \text{oO}) || (\text{oS}, \text{oO}) \\
(\text{oS}) &= > (\text{sS}, \text{oS}, \text{oO}) || (\text{sS}, \text{oO})
\end{align*}
\]

The unary positions (oO), (sS) and (oS) are all thematizing the corresponding dyads. Hence, the unary monads are involved into two aspects based on the binarity of the founded dyads of the triad. Therefore, the monads shall be indexed by the index set={1, 2}.

Gunther’s concept of founding relations found some application in general systems theory (Alfred Locker). The formalism might have its own value from a descriptive viewpoint but is not well prepared for operative transformations. One attempt to formalize the epistemic model one step further happen with the application of Gunther’s Kontextwertlogic (Contextvalued logic), as opposed to Stellenwertlogik (place-valued logic) (cf. Kaehr 1978, Baldus 1982, Grochowiak 1979).

A new attempt to formalize the idea of founding relations is proposed by the diamond approach which takes into account the simultaneity of the model and its foundation. It also reflects the fact, that a foundation of an operation is localized on a different level of abstraction. The activity of modeling and the activity of founding are complementary activities demanding different kinds of abstractions. Hence, any applicative iteration of the model on itself is not fulfilling the criteria of foundation.

3.1.1. Chinese Ontology and Diamonds

The idea of in-sourcing the matching conditions into the definition of diamonds tries to realize the two postulates of Chinese Ontology, the permanent change of things and the endness or closeness of situations. That is, diamonds should be designed as structural explications of the happenstance of compositions and not as a succession of events (morphisms). More exactly, diamond are contemplating the interplay of acceptional and rejectional thematizations. Thus, morphisms with their matching conditions and composability are in fact of secondary order for the understanding of diamonds.

The complementarity of construction and verification, which is happening at once and not in a temporal delay, is a consequence of the finiteness and dynamics postulate of
polycontextural "ontology". This simultaneous interplay is based on the insight that a delayed verification (or testing in programming) would not necessarily verify the construction in question because, at least, the context will have changed in-between. Delayed verification is possible only in the very special case of frozen dynamics.

In other words, in a changing open/closed world, the activities of construction and verification (of correctness and relevance) have to happen at once. Otherwise, because the conditions might have changed, the relevancy of the construction to be verified would have to be verified itself, again, and this ad nauseam. Obviously, the statement is not about/against the stability of the construction (program, system, agreement, contract), this might be rock solid, but about the relevancy of the rock solid construction.

(In therapy, even by constructivists, this delayed checks are called “reality check”. Nearly everytime, such a reality to be checked has escaped any relevance.)

**In-sourcing the matching conditions**

Diamond strategies are offering a fundamentally different approach. Each step in a diamond world has simultaneously its counter-step. Hence, each operation has an environment in which a legitimation of it can be stated. The legitimation is not happening before or after the step is realized but immediately in parallel to it.

Morphisms are representing mappings between objects, seen as domains and codomains of the mapping function. Hetero-morphisms are representing the conditions of the possibility (Bedingungen der Möglichkeit) of the composition of morphisms. That is, the conditions, expressed by the matching conditions, are reflected at the place of the heteromorphisms. Hetero-morphisms as reflections of the matching conditions of composition are therefore second-order concepts realized "inside" the diamond system.

Morphisms and their composition are first-order concepts, which have to match the matching conditions defined by the axiomatics of the categorical composition of morphisms. But these matching conditions are not explicit in the composition of morphism but implicit, defined "outside" of the compositional system. Hence, in diamonds, the matching conditions of categories are explicit, and moved from the "outside" to the inside of the system. In this sense, the rejectional system of hetero-morphisms is a reflectional system, reflecting the interactions of the compositions of the acceptional system. Heteromorphisms are, thus, the "morphisms" of the matching conditions for morphisms.

3.1.2. Duplicity of reflection

This approach, to model the founding relation in the framework of diamond theory might be achieved with a decomposition of the founding relation into its parts: monadic and dyadic relations as the rejectional parts of the diamond interplay between model and foundation, i.e. acceptional (categorical) and rejectional (saltatorical) thematizations. The founding operation itself, \( r \), which has unary and binary operands, e.g. \( O \in \text{unary}, S^r : S^0 \in \text{binary} \), is not implemented and involved into the definition of the triadic model itself as it is introduced by Gunther.

Funding relations and structural relations are complementary and antidromic in their orientation. If there is something like a "Duplizität des Ich" (Fichte) (A duplicity of the ego) then such a duplicity is of interest only if this duplicity is a simultaneous duplicity. A successive hierarchy of different levels of epistemic reflection, as it is supposed in Anglo-Saxon philosophy and computational reflection, belongs to a strictly different paradigm of thinking. Similar intricate situations of duplicity of consciousness had been discovered by Edmund Husserl with his distinction of retention and protention.
of the temporal structure of reflectional acts.

**3.1.3. Subjectivity as a founded triadic model**

"What we still have to consider is the relation any of the three terms $S^S$, $O$ and $S^O$ may assume to the relation which holds between the other two terms. From a purely combinational view point three possibilities exist for a demanded relation ... $r^F$ ... they are:

$$S^S r^F (O \rightarrow S^O)$$
$$O r^F (S^O<-> S^S)$$
$$S^O r^F (S^S-> O)$$

Formally speaking it is the relation any of the two realizations of $S$, namely $S^S$ or $S^O$, may have toward the connection of the other $S$ and $O$. We call this the founding relation ($r^F$) because by it, and only by it, a self reflective subject separates itself from the whole Universe which thus becomes the potential contents of the consciousness of a Self gifted with awareness. In contrast to it the classic relation $O r^F(S^O<-> S^S)$ is still a founding relation but not for consciousness.

But this claim also extracts from the "outside" observer, $S^S$ an interesting admission. He will state that, seen from his vantage point, the inclusive disjunction does not only hold in the case of:

$$S^S r^F(O \rightarrow S^O) . \lor . S^O r^F(S^S-> O)$$

but also in the other two cases:

(1) $S^S r^F(O \rightarrow S^O) . \lor . S^O r^F(S^S-> O)$
(2) $S^O r^F(S^S-> O) . \lor . O r^F(S^S<-> S^O)$
(3) $S^S r^F(O \rightarrow S^O) . \lor . O r^F(S^S<-> S^O)$

provided, of course, that he uses a two-valued logic.

But in doing so he realizes by self-reflection that he has committed a momentous logical mistake. Since in classic logic only two values are available for the determination of the distinction between subject and object, it is impossible to describe the *triadic* relation between the subjective subject; the objective subject and the object.

This investigation intends only to show that the concept of *Totality* or *Ganzheit* is closely linked to the problem of subjectivity and trans-classic logic and that it is based on three basic structural relations:

- an *exchange* relation between logical positions
- an *ordered* relation between logical positions
- a *founding* relation which holds between the member of a relation and a relation itself.

We are now able to establish the fundamental law that governs the connections between exchange, ordered and founding relation.

Thus we may say: the founding-relation is an exchange relation based on an ordered relation. But since the exchange relations can establish themselves only between ordered relations we might also say: the founding-relation is an ordered relation based
on the succession of exchange-relations. When we stated that the founding relation establishes subjectivity we referred to the fact that a self-reflecting system must always be: self-reflection of (self- and hetero-reflection)."
(Gunther, Formal Logic, Totality and The Super-additive Principle, 1965) in:

3.1.4. Semiotic triads

Semiotic triads occur as morphisms between the instances I, O, M and their combinations, called graph theoretic sign models.

1. (I-->O -->M)            4. (O-->M-->I)
2. (M-->O-->I)             5. (I-->M-->O),   (M-->I-->O)
3. (I-->M--> O)            6. (O-->I-->M).

"In 1966, Günther showed that the three reflexive categories of a three-valued logic, objective subject (oS), object (O) and subjective subject (sS) correspond (in this order) with the semiotic categories of medium (firstness), object (secondness) and interpretant (thirdness)."
(cf. Toth 2008, p. 64):
oS <=> M ≡ (.1.)
O  <=> O ≡ (.2.)
sS <=> I ≡ (.3.)

3.1.5. Gunther's journeys

Triadic semiotics (Bense, Toth) and triadic epistemology (Gunther). Also Gunther's approach and semiotic triads are fitting, at least at a first glance, well together, Gunther's epistemological triadism shouldn't be taken too seductively, because (t)his obsession lasted only for a short and specific time of Gunther's speculations. In the early 60s, the dialogical concept was replaced by a much more socialist distribution of subjectivity over a mass of 'subject centres' (Chinese Cultural Revolution).

"To sum it up:
A non Aristotelian or trans-classical logic is a system of distributed rationality. Our traditional (two valued) logic presents human rationality in a non distributed form. This means: the tradition recognizes only one single universal subject as the carrier of logical operations.

A non-Aristotelian logic, however, takes into account the fact that subjectivity is ontologically distributed over a plurality of subject centres. And since each of them is entitled to be the subject of logic human rationality must also be represented in a distributed form. The means to do this is to interpret many valued structures as place-value systems of our two valued logic." (Gunther 1962)

In a German paper, 1965, Gunther writes: “Wir sind zum Übergang zu einer vierwertigen Logik genötigt, in der nicht nur Subjekt-überhaupt und Objekt-überhaupt durch logische Werte vertreten sind, sondern in der U sowohl als S₁, S₂, S₃ ontologische Instanzen repräsentieren, von denen jede Vertretung duch einen eigenen Wert beansprucht.”

Some years later in 1968, Gunther developed a general theory of mediation where anthropological roots had been erased in favor of the history of the world as such - with or without human beings.

Furthermore , 2 years later, in his "Die historische Kategorie des Neuen", in Moscow in favor for Change, his theory of polycontexturality is strictly neutral to any specific
interpretation. Neither I, Thou, It or other subjectivity constructs are appearing in the historical development of the New.

http://www.vordenker.de/ggphilosophy/gg_category.pdf

The whole conceptual story is well sketched at:
Ditterich, Kaehr: Einübung in eine andere Lektüre
http://www.vordenker.de/ggphilosophy/kaehr_einuebung.pdf

Nevertheless, it seems that even today it would be a revolution to realize a working 3-contextural scientific paradigm and technology (of computing and social organizations).

Again, the proposed classical theory of triads is formulated in the framework of a binary and dichotomous First-Order Logic., i.e. n-ary relations are logically reducible to binary relations. Hence, it achieves a simulation of trichotomic logic and never a realization. (Cf. Ternary Computers, Moscow)

What do we learn? As Max Bense mentioned correctly, Gunther was a Laborphilosoph (lab philosopher) and not a Kathederphilosoph (lectem philosopher) - this is true, despite the fact that each attempt to his philosophy, albeit only a fragment, was declared with absoluteness. Asked some month later about his theoretical advances and some immanent problems of it, he even didn’t remember it. This surely was an exaggeration, but he was, again, some steps further on. And so on.

3.1.6. Toth’s founding strategy

Toth’s semiotic modeling of Gunther’s founding relation is of importance, not only for systematic semiotics alone but for applications in computational semiotics and the triple-approach for semantic implementations in the project of a Semantic Web or Web 3.0.

Nevertheless, both, Gunther and Toth, are stressing on the successive, iterative or orthogonal structure of the idea of founding logic and semiotics. Because the basic triadic structure to be founded remains untouched, the whole approach might be more an application then a foundation.

This analysis is confirmed by Toth’s statements:
"In accordance with Günther (1991), these superizations [based on categories and relations] are based on semiotic orthogonality.” (Toth 2008)

Superization, obviously, is a special application and is immanent of semiotics, not changing anything in its fundamental definition.

"From the logical standpoint, the latter means that the “Thou” founds the order relation between an “I” and an “It” (OS --> (SS --> O)), that an “I” founds the order relation between an “It” and a “Thou” (SS --> (O --> OS)), and finally, that an “It” founds the exchange relation between an “I” and a “thou” (O --> (SS <-->OS)).” (Toth 2008)

All parts of the founding relations are unchanged parts of the logical or epistemic model. The different roles of the instances might be used but not represented. That is, e.g. “It” as a founding point of view and “It” as a founded element of the model are technically not distinguished in the semiotic approach. This fact is based on the triviality that the model and its founding relations don’t have the necessary structural complexity. That is, at least two variables would be needed to model the different roles of the elements depending on their context. Context-value logic (Kontextwertlogik) was introduced just for this purpose (Gunther 1968).
There is up to now no equivalent at all to find in Bensean semiotics.
Some more approximations

\[ \text{trijoin}_{\text{dom}}\left(\text{trijoin}_{\text{dom}}\left(\left\{ R, r \right\}, \left\{ S, s \right\}, \left\{ T, t \right\} \right)\right), \text{trijoin}_{\text{dom}}\left(\left\{ R, r \right\}, \left\{ S, s \right\}, \left\{ T, t \right\} \right), \text{trijoin}_{\text{dom}}\left(\left\{ R, r \right\}, \left\{ S, s \right\}, \left\{ T, t \right\} \right) \]

\[ = \text{trijoin}_{\text{dom}}\left(\left\{ S, r \right\}, \left\{ S, s \right\}, \left\{ S, r \right\}, \left\{ S, s \right\}, \left\{ S, r \right\}, \left\{ S, s \right\} \right) \]

Diamond Relations

Sketch of a theory of diamond relations

Rudolf Kaehr Dr.@
ThinkArt Lab Glasgow

Abstract

Because of their concreteness, the complexity of relations is more structured and is not always tackled by the axioms or properties of mathematical categories. E.g. the categorical properties of commutativity and transitivity are not necessarily holding for relations.

As an application, relations and the category of PATH as proposed by Pfalzgraf is presented. Diamond relations and a diamond version of PATH, i.e. JOURN (journey), based on diamond set theory, is sketched.

How to introduce intransitivity (non-commutativity) in category theory? Two approaches are presented: Pfalzgraf’s generalized morphisms which are re-establishing categorical commutativity on a generalized level of relations and a sketch of polycontextural diamond constructions which are introducing different types of non-commutativity on the level of a generalized (disseminated) paradigm of categoricity.

1. Diamond relations

1.1. Set-theoretical relations

1.1.1. Composition of relations

A relation from set $A_0$ to a set $A_1$ is a triple

$(A_0, R, A_1)$ with $R \subseteq A_0 \times A_1$.

its composition with $(B_0, R, B_1)$ is defined iff $A_1 = B_0$.

The composition of two relations $R: A \rightarrow B$ and $S: B \rightarrow C$ is given by:

$[a, c] \in S \circ R$ iff for some $b \in B$, $(a, b) \in R$ and $(b, c) \in S$.

That is:

$[a, c] \in S \circ R \iff \exists b \in B : (a, b) \in R \land (b, c) \in S$.

Obviously, sets like $A$, $B$ and $C$ with their elements $a$, $b$ and $c$ belong to the universe of sets $U$: $A, B, C \subseteq U$.

1.1.2. Composition of morphisms

“A binary operation $o$, called composition of morphisms, such that for any three objects $a$, $b$, and $c$, we have $\hom(a, b) \times \hom(b, c) \to \hom(a, c)$.

The composition of $f: a \to b$ and $g: b \to c$ is written as $g \circ f$ or $gf$ (some authors write $fg$), governed by two axioms: Associativity and Identity.” (Wiki)

Mostly, the first-order logic and set theoretical notions to build category theoretical constructions, are not formalized in the sense of formal logic and set theory.

$A \overset{f}{\to} B \circ B \overset{g}{\to} C \Rightarrow A \overset{gf}{\to} C$, with $\text{cod}(f) = \text{dom}(g)$
Diagram

\[ A \rightarrow B \rightarrow C \]

**Category theory as a first-order theory**

1. **Transitivity of relations**

   \[ \forall a, b, c : aRb \land bRc \Rightarrow aRc \]

   "In mathematics, a binary relation \( R \) over a set \( X \) is transitive if whenever an element \( a \) is related to an element \( b \), and \( b \) is in turn related to an element \( c \), then \( a \) is also related to \( c \)." (Wiki)

1. **Intransitivity of relations**

   \[ \neg \forall a, b, c : aRb \land bRc \Rightarrow aRc : \text{intransitivity} \]

   \[ \forall a, b, c : aRb \land bRc \Rightarrow \neg aRc : \text{Antitransitivity} \]

1. **Intransitivity for composition**

   \[ \forall a, b, c : \text{hom}(a, b) \times \text{hom}(b, c) \rightarrow \neg \text{hom}(a, c) \]

   \[ \forall a, b, c : \text{hom}(a, b) \times \text{hom}(b, c) \rightarrow \text{hom}(a, c) \]

1.2. **Diamond theory of relations**

1.2.1. **Diamond relation**

Does this construction make any sense for category theory? Obviously not. It doesn't accept the main definition of categorical composition of morphism.
Diamond relations are defined over the pluri-verse of acceptional and rectional sets.

Classical (acceptional) binary relation: \( R \subset (X \times X) \)

Non-classical (reactional) binary relation: \( r \subset (X \times X) \)

Diamond binary relation: \( (R, r) \subset (\pi(x, x) \circ (X, x)) \)

\[
\begin{align*}
(\pi(x, x) \circ (X, x)) & \quad \text{iff} \\
R \subset (X \times X) & \quad r \subset (X \times X)
\end{align*}
\]

For each binary relation \( R \subset X \times X \), with \( X \in U \), there is a complementary unary relation \( r \subset (X, x) \) with element \( x \in U \).

For each ternary relation \( R \subset X \times X \times X \), with \( X \subset U \), there is a complementary binary relation \( r \subset (x, x) \) with \( x \in U \).

\[
(\pi(x, x) \circ (X, x)) \quad \text{DiamRel:}
\]

\[
R \in \text{Cat}, \quad r \in \text{Sat}
\]

\[
(\pi(x, x)) \quad \text{Rel}(x) \quad \text{rel}(x)
\]

\[
1.2.2. \quad \text{Diamond composition of relations}
\]

**Diamond Composition of Relations**

A relation from tuple \( (A^0_0, A^0_2) \) to a tuple \( (A^1_0, A^1_2) \) is a 2-triple \( ((A^0_0, A^0_2), R^{1,2}, (A^1_0, A^1_2)) \) with \( R^{1,2} \subset (A^0_0, A^0_2) \times (A^1_0, A^1_2) \).

Its composition with \( ((B^0_0, B^0_2), R^{1,2}, (B^1_0, B^1_2)) \)

\[
\left[ \begin{array}{c}
\sigma(A^0_0) = \sigma(B^0_0) \\
\sigma(A^0_2) = \sigma(B^0_2) \\
\sigma(A^2_1) = \sigma(B^2_1) \\
W_1 = x_2 \\
A^1_0 = B^1_0
\end{array} \right]_{\text{Diam}}
\]

is diamond-defined iff

\[
\left[ \begin{array}{c}
\sigma(A^0_0) = \sigma(B^0_0) \\
\sigma(A^0_2) = \sigma(B^0_2) \\
\sigma(A^2_1) = \sigma(B^2_1) \\
\omega_1 = x_2 \\
A^1_0 = B^1_0
\end{array} \right]_{\text{REL}}
\]
2. Category PATH

2.1. Motivation

Diamond motivation

From the point-view of diamonds, the question about non-identitive, non-commutative and non-transitive compositions for diamonds might arise. Non-transitivity is a well known property for so called “real life” situations. Again, a first observation to remind, is the fact, that in contrast to classical logic, the operator “non” has many well-defined appearances in polycontextural logics. Non-transitivity in diamond theories, thus, is not simply a total negation or rejection of transitivity but the acceptance of a plurality of different kinds of transitivity, enabling many kind of specific non-transitive relations.

Non-transitivity appears naturally for relations. Categories are by definition transitive (commutative). Hence, intransitivity for categories can be introduced only as a secondary concept. On the other hand, intransitivity for relations might be transformed to transitivity by a kind of a generalization or an abstraction to generalized relations, i.e. “a more general type of morphism” based on the difference of direct and indirect arrows (Pfalzgraf).

It is based on a very different paradigm to ask: “How to introduce intransitivity on the epistemological level of the definition of categories as such?”

It shall be shown, say sketched, that such a basic interplay of transitivity and different forms of non-transitivity is accessible in the framework of a polycontextural diamond category theory.

Road Map Metaphor
"Let us consider, for illustration, a simple practical example of real life: Looking at general relational structures is quite natural since transitivity and even reflexivity are not always existent in applications.

As a practical example let us look at a road map where the nodes (objects) are towns and the arcs (arrows) are road connections, then not every pair of towns has a direct connection (arrow), in general. Therefore, generally, starting from a point we have to follow a path of direct road connections passing several nodes (towns) before we can reach a goal." (Pfalzgraf) [my emph]

Pfalzgraf gives an example about direct connections between towns. The same observation holds for most intensional verbs, like win, love, hate, etc., e.g. A loves B, B loves C. Does A loves C hold necessarily? Obviously not.

Pfalzgraf's strategy to keep transitivity by generalization could be paraphrased as: A loves B, B loves C, A hate C, then, by generalization from intransitivity to transitivity:
A is-in-emo-relation to B,
B is-in-emo-relation to C, hence,
A is-in-emo-relation to C.

On the other hand, if A is connected with B, and B is connected with C, then A is connected with C, too. At least in a stable world, where the definition of connection is not suddenly transforming itself.
But is this reflection on intransitivity matching the level of categorical abstractions, like morphisms, compositions, matching conditions? Obviously not!

Such examples are localized on the level of relational algebra and logic, i.e. based on set theoretical and not on category theoretical assumptions.

Pfalzgraf gives a relational definition of situations where transitivity and reflexivity doesn't hold. Then he extends his “CAT modeling approach” to “contain arbitrary relations”. On the base of this relational concept he abstracts the category PATH.

Transitivity gets re-established with Pfalzgraf's approach by the more general abstraction of “consecutive arrows” in contrast to “direct arrows”. In the example below, “x-->z” is a direct arrow (morphism) which is not covered in the relational approach, but the consecutiveness of arrows “x -->y -->z” as such is considered as a generalized morphism Mor(x,z).

The proposed “extension” of categories, based on the distinction “direct” versus “consecutive” arrows (morphisms), towards a category of relations seems to be an application of “pure” category theory to the theory of relations and not in itself a categorical extension, but an application. At the end, all gets saved, back home in the category PATH.

Activity Map Metaphor
Instead of connecting towns, i.e. objects, the diamond approach is focusing on connection activities, i.e. arrival/departure-activities, of journeys between towns. The set- and object-aspect of towns is secondary to the activities of coming (arriving) and going (departing). It is just this focussing on activities which is enabling the discovery of the concept of hetero-morphism and the construction of saltatories that are complementary, and not simply dual, to categories.

First- and second-order thematizations.
Now, thinking seems to be an activity too. Hence, the process of thinking might be connected, step by step. Steps are represented by morphisms, morphisms are informational, information is based on first-order observation. The process of composition isn’t in focus. In focus are morphisms based on objects. But objects are moved into the background in favor of morphisms. Therefore it is strict forward to think of non-transitive connections of morphisms as a morphism. This is a kind of an abstraction towards a “more general” concept of morphism. This abstraction is abstracting in two directions, one from the objects and one from the composition of the less general, i.e. ordinary morphisms.

"We point out here that in our definition of agents human agents are included." (Pfalzgraf, 07, p.33)

On this level of abstraction it is not only generous but necessary to include human actors together with any other actors into the general approach of MAS. As far as we reduce human actions to non-reflectional roles, like using a mobile phone, e-Business, this reduction is appropriate. But as usual, the claims are much higher.
If thinking the process of thinking is understood as something different to the mere process of thinking (of something) then, such a second-order thinking is not properly modeled by morphisms but by a reflection on the conditions of morphisms which are, in this scenario, compositions, the operation to compose morphisms. The alter of morphisms are compositions. But that is demanding for a radically new abstraction. An abstraction which is not objectivizing compositions to morphisms of ordinary or general abstraction, but is keeping the processuality of the process in its own right and domain.

The argumentative figure to this difference is this: classic thinking is thinking of something. Therefore, for classical thinking, second-order thinking is thinking of thinking of something, i.e. thinking of something and this something is a “thinking of something”, hence, still accessible to thinking as thinking of something - and nothing else. As a result, classical thinking is inevitable connected with the problem of infinite regress of its meta-levels (type theory, meta-circularity).

Transclassical thinking insists on the structural difference between thinking of something and thinking of thinking as the process of thinking (of something). It is the processuality which isn’t caught by the ontology of something, even if this something is not stubbornly thought as an identical object but as a temporal object or process (Whitehead). If there will be, one day, something like a Semantic Web, it will not be based on morphisms or generalized morphisms.

Second-order thinking or, as it is called more properly, transcendental logic (Kant, Husserl, Gunther), is not formalized by category theory or relational algebra and logic.

The only account I’m aware of is the approach I proposed myself as diamond category theory. Diamond theory takes thinking a step further than polycontextural logic as it was introduced by Gunther as a first step towards a formalization of dialectics and transcendental logic and as it was further developed in the last decades by my own work.

As the transcendental logical tradition (Kant, Fichte, Schelling) pointed out, thinking is doubled. Fichte calls it the “Duplizität des Ich”. The process of thinking, which is thinking of thinking, is parallactic and antidromic. This exactly is what diamond theory discovered. The crucial difference is that diamond theory is formal and operative, albeit in a new sense of the terms but nevertheless well connect to the tradition of mathematical thinking, and not speculative descriptive like the transcendental logic forerunner.

**Diamond non-transitivity**

What could be a reasonable extension of category theoretical definitions per se introduced from a diamond approach? The strategy, that has to be excluded first, is to go back to application, concretization and other methods, like fiberization, which are, despite their productivity, leaving the level of category theoretical abstractions. The only chances I see at the time for a structural enhancement of categorical notions, beyond fibered and n-categories, seems to be sketched by the diamond approach to compositionality of morphisms, i.e. the complementarity of categories and saltatories.

**Categorical motivation**

Following Jochen Pfalzgraf

"For practical reasons - in order to reach a large area of applications - we extend our CAT modeling approach to arbitrary relations (X,R). In such a case, we are not able to associate directly a category to the relation as we did it before since transitivity, reflexivity do not hold, in general.

"But from the categorical perspective again we interpret a relational structure as a certain diagram of arrows “visualizing” the given relations between the objects which form the “nodes” of the diagram. It turns out that we can always “embed” such a diagram in an associated PATH-category having comparable behavior as the category associated to a reflexive, transitive relation, although being a little “bigger” concerning the morphism structure.

"We point out: The introduction of the associated category PATH allows to use and apply all the modeling principles and constructions provided by CAT in the corresponding situations."

**2.2. Formal description**
"For the technical definitions, again let \( R \subseteq X \times X \) or \((X, R)\) denote a (general) relation. We associate to it the following category denoted by \( \text{PATH}(X, R) \) or just \( \text{PATH} \) for short, if no confusion can arise.

"The objects are the elements \( x \in X \) and arrows (morphisms) are defined by sequences (paths) of adjacent arrows. That means, there is always a morphism \( x \to y \), if \( (x, y) \in R \) (or \( xRy \)), but if we have arrows (morphisms) \( x \to y \) and \( y \to z \), then, in general we do not have a “direct arrow” \( x \to z \), since the relation need not to be transitive. But what we can always do is forming a sequence (path) of consecutive arrows, like \( x \to y \to z \) in the previous case. This is then a morphism of a more general type between \( x \) and \( z \).

"More generally, we can have (finite) sequences denoted for example by \( x_0 \to x_1 \to \ldots \to x_n \) which is a morphism in \( \text{Mor}(x_0, x_n) \) in the new sense of our definition, but can also be interpreted as the composition of other morphisms which will be represented by adjacent parts of that whole path.

"In a category normally we need the identity arrow \( \text{id}_x \) for each object \( x \). We can add this as a requirement if there is really a necessity from a theoretical viewpoint; in practice this may be irrelevant.

"In \( \text{PATH} \) it can be the case that there exists more than one path between two nodes \( a \) and \( b \), therefore in \( \text{PATH} \) we can have for the sets of morphisms \( |\text{Mor}(a, b)| > 1 \), in general, in contrast to the category which is associated to a reflexive, transitive relation as considered before. Based on these considerations we can see that \( \text{PATH} \) becomes a category.” (Pfalzgraf)

### 2.2.1. Formal description of \( \text{PATH} \)

"Let \( R \subseteq X \times X \) denote a general relation. We associate with it the category denoted by \( \text{PATH}(X, R) \), \( \text{PATH}(X) \) or just \( \text{PATH} \).

**Objects:** Elements \( x \in X \).

**Arrows, Morphisms:** Sequences (paths) of consecutive arrows.

"This defines composition of arrows, in a natural way (concatenation of consecutive arrows) and this composition is associative. The identity arrow \( \text{id}_x \), with respect to each object \( x \in X \), will be assumed to exist (“tacitly”) by definition.

"There is a morphism \( x \to y \), iff \( xRy \).
In general, for arrows \( x \to y \) and \( y \to z \), we do not have a “direct arrow” \( x \to z \) (the relation can be not transitive) - this causes no problem.

"We can always form a sequence (path) of consecutive arrows, like \( x \to y \to z \).
This is a morphism of a more general type between \( x \) and \( z \). More generally, we can have (finite) sequences, for example \( x_0 \to x_1 \to \ldots \to x_n \) (a path), this is a morphism in \( \text{Mor}(x_0, x_n) \) in the new sense of our definition. It can also be interpreted as the composition of other morphisms being represented by adjacent parts of the long sequence. Thus, \( \text{PATH} \) is a category.” (Pfalzgraf)

### 3. Diamond of JOURNs

#### 3.1. The journey map metaphor

Paths in diamonds are not exactly path in the sense of the category \( \text{PATH} \) but journeys. Thus, diamond paths are building diamond JOURNs. Hence, \( \text{JOURN} \) is not a category but a diamond.

"To practice the complementarity of the movement is not as simple as it sounds. You have to have one eye in the driving mirror and the other eye directed to the front window and, surely, you have to mediate, i.e., to understand together, what you are perceiving: leaving and approaching at once. And the place you are thinking these two counter-movements which happens at once is neither the forward nor the backward direction of your journey. It’s your awareness of both. Both together at once and, at the same time, neither the one nor the other. It is your arena where you are playing the play of leaving and arriving."

"This complementarity of movements is just one part of the metaphor."
Because life is complex, it has to be composed by parts. Or it has to be de-composed into parts. We may drive from Dublin to Glasgow and then from Glasgow to London to realize our trip from Dublin to London. This, of course, is again something extremely simple to think and even to realize. But again, there is a difference to discover which may change the way we are thinking for ever.” (Kaehr, The Book of Diamonds, Intro)

http://rudys-diamond-strategies.blogspot.com

JOURN’s catalogue of journeys

There are structurally different kinds of journeys on offer.
1. PATH is a very special type of journey. It is an intra-contextural journey in a single contexture without structural environment. Hence, properly formalized as a category.
2. This situation might be distributed. Journeys in different but mediated contextures are possible. Still isolated and each thus intra-contextural.
3. A new kind appears with possible switches (permutation) and transjunctional splitting (bifurcation) simultaneously into paths of different contextures. Still without complementary environment in the sense of diamond theory.
4. Now, each contexture, even an isolated mono-contexture, might be involved into itself and its environment. This happens for diamonds, which are containing antidromically oriented path in categorical and saltatorial systems. Such journeys ar group-journeys with running into opposite directions.
5. Here, a new and risky journey is offered by the travel agency by inviting to use the bridging rules between complementary exceptional and rejectional domains of categories and saltatories of a diamonds. All that happens intra-contexturally, i.e. diamonds are defined as the complementarity of an elementary contexture.
6. Obviously, diamond journeys might be organized for advanced travellers into polycontextural constellations. Hence, there are transcontextural transitions between diamonds to risk. Interestingly, such journeys might be involved into metamorphic changes between exceptional and rejectional domains of different contextures of the polycontextural scenario.

Further Metaphors

As a metaphor, the idea of colored contexts, each containing a full PATH-system, involved in interactions between neighboring contexts, might inspire the understanding of journeys in pluri-labyrinths of JOURN.

Such journeys are not safely connected in the spirit of secured transitivity but are challenging by jumps, salti and bridging and transjunctional bifurcations and transcontextural transitions.

This metaphor of colored categories, logics, arithmetic and set theories gets a scientific implementation with real world systems containing incommensurable and incompatible but interacting domains, like for bio- and social systems.

"Observation: An arbitrary binary relation R on X induces a corresponding arrow diagram D, "visualizing" the given relations between objects by corresponding arrows. Vice versa, a given arrow diagram D induces (or defines) a corresponding binary relation R on the set of elements (nodes) of D in the obvious, natural way, i.e. a specific arrow x → y in D defines xRy. In these situations there is always an associated Cat PATH.” (Pfalzgraf, ACCAT-TutorialSKRIPT, p. 32, 2004)

3.2. Formal description of JOURN

Let $R^2 \subseteq (A^1, A^2) \times (A^3, A^4)$, denote a general bi-relation. We associate with it the diamond denoted by JOURN((X,x), $R^2$), JOURN(X,x) or just JOURN.

Bi-objects: Bi-Elements $(X,x) \in (X,x)$.

Morphisms: Sequences (paths) of consecutive arrows,

Hetero-morphisms: counter-sequences of antidromic arrows.

Complementarity: Category/Saltatory

JOURN is not a product of PATH, i.e. JOURN != PATH x PATH but a complementary (and not a dual!) interplay between PATH and co-PATH:

JOURN = comp(PATH, PATH)

There is a morphism X → Y, iff XRY ∈ Cat.

There is a hetero-morphism x → y, iff xry ∈ Salt.

There is a diamond if [Cat; Salt].

$R^2 \subseteq (A^1, A^2) \times (A^3, A^4)$

$[R^2] \subseteq (A^5, A^6) \times (A^7, A^8)$
### 3.2.1. Monocontextual diamond journeys

Diamond journeys might realize intransitivity by changing between categories and saltatories of a diamond. Also transitivity is established, taken in isolation, for both, the categorical composition of morphisms in a category and for the jump-operation (saltisition) of hetero-morphism in saltatories, journeys might follow nontraditional paths between categories and saltatories by exploiting the possibilities opened up by the bridging operations.

"Jumping operations are the main operations for hetero-morphisms. A new abstraction, additionally to composition and saltisition, is introduced for the bridging of categories and saltatories. Bridging has two faces: bridge and bridging."

#### Collecting terms

**Category:** composition based on matching conditions (coincidence)

**Saltatory:** saltisition based on jumping conditions

**Interactionality:** bridge, bridging, transversality, paralléllity based on bridging conditions (difference).

#### Possible chain of operators

- **composition** \((\circ)\) produced by morphisms, matching condition, domain, codomain,
- **saltisition** \((||)\) produced by complementation (difference) of composition,
- **bridge** \((\wedge)\) produced by composition and difference from category and saltatory,
- **bridging** \((\cdot)\) produced by difference from bridge.

As a consequence, the composition \((f \circ g)\) and the saltisition \((k || l)\) are mixed to \((l || k) \circ g)\).

Bridging vs. jumping shows clearly that not only what is achieved matters but how it is achieved, i.e. by bridging or by jumping. Each jump in a saltatory has an inverse morphism as a bridge in a category.

#### Properties of bridging

</table>
3.2.2. Polycontextural journeys

Polycontextural category theory is enabling journeys between different contextures covering autonomous categories. This might happen in parallel or in cycles. Multiple parallel and cyclic journeys might running concurrently in the polycontextural matrix of disseminated categories.

For each category of a contexture an intra-contextural path might be realized and ruled by PATH. An interplay between local and global thematization of the scenario, enabling distancing and zooming in, is describing intra- and poly-contexturality of JOURN.
That is, for all 3-contextural parallel path-constellations (C3a) there is a cascade-journey (C3b) in (C3a).

\[
\begin{align*}
\text{C3a} & : (3 - \text{contextural parallel}) \\
\forall \ x \ \forall \ y : & \left( \exists \ z : K^2 (x, y, z) = (C^3 (x) = D^2 (y)) \right)
\end{align*}
\]

3.2.3. Polycontextural diamond journeys

That is, for all 3-contextural parallel path-constellations (C3a) there is a (cascade) cyclic-journey (C3c) in (C3a).

\[
\begin{align*}
\text{C3c} & : (3 - \text{contextural cycle}) \\
\forall \ (z) \ x \ \forall \ (y) : & \left( \exists \ z : K^3 (x, y, z) = (C^3 (x) = D^3 (y)) \right), \\
& \left( E^3 z : K^2 (x, y, z) = (C^3 (x) = D^3 (y)) \right), \\
& \left( E^3 z : K^1 (x, y, z) = (C^3 (x) = D^3 (y)) \right).
\end{align*}
\]

That is, for all 3-contextural parallel path-constellations (C3a) there is a (cascade) cyclic-journey (C3c) in (C3a).
Is the diamond construction working for non-commutative compositions?
Diamond category theory was up to now based on the commutativity of composition of morphisms \( f \) and \( g \), i.e. the coincidence relations for the composite \( fg \) was restricted to transitivity. Diamond structures are abstractions from compositions and are not depending on special properties of compositions. Hence, diamondization of relational concepts is well founded in the abstraction from composition in general.

### 3.2.4. Interplay between polycontextural diamond journeys
4. Diamond set theory

The concept of relation and its relational algebra is based on set theory. This wasn’t always the case (Peirce). But today, set-theory based relation theory is well established.

Diamond relation theory, therefore, is based on diamond set theory. Diamond set theory is only in its very beginnings.

5. Architectonics of disseminated categories

5.1. Rhizomatics

The question behind the proposed constructions for non-commutative (diamond) category is unmasking a deeper structure of category theory not yet mentioned explicitly. That is: What is the general architectonics of categorical constructions? Or: On which architectonical decisions are categories based?

There are first answers to learn in the papers “ConTeXtures” and “PolyLogics”.

5.1.1. Category theory

The leading metaphor of category theory can be found in the use of linerarily ordered compositions of arrows.

“A category can be regarded as a directed graph with structure.”

They are symbolizing an information flow from arrow to arrow.

"...the unifying idea is that of 'information flow'.

Hence, ‘Ordinary category theory uses 1-dimensional arrows -->.

Higher-dimensional category theory uses higher-dimensional arrows.’” (Leinster, 2003)

5.1.2. n-Category theory

In contrast to category theory the leading metaphors of n-category is based in topology. With that, new fundamental or basic topologies or architectonics for categories are naturally motivated and constructed.

“The natural geometry of these higher-dimensional arrows is what makes higher-dimensional category theory an inherently topological subject.” (Leinster, 2003)

Some further ideas are developed in the paper: “Categories and Contextures”

5.1.3. Disseminatorics

Dissemination of categories over a kenomic matrix is not only topological but takes into account the mediation mechanism of proemiality instead of the quite vague matching conditions of category theory.

It could be stated as a theorem, that all possible relational constellations of combinatorial tree-structures can be represented as architectonics of disseminated categories.
Hence, all relational constellations, with commutative and diverse non-commutative properties, might serve as equal architectonics for disseminated, i.e. distributed and mediated, categories.
There is no prime structure.
A Birkhoff arithmetics of such skeletal structures might be considered.

Obviously, the game starts with the number 4. All other cases are structurally equivalent.
Especially for the number 3, there are no formal criteria to distinguish the skeletal architectures of a line from the architectures of a star, both are coinciding.

"Only for the elementary case of m=3, star and line structures are coinciding. This simple structural coincidence may be the hidden reason of profound epistemological controversies in philosophy and sociology." (cf. Kaehr, Contextures, 2005, Materialien 1978)

With the number 4, the skeletal difference of line- and star-structure is accessible. As the combinatorial table, below, for skeletal structures shows, an interesting coincidence of complexity and structures is given for the number 6. For complexity $m\geq 7$, the number of structures is increasing, $\text{structures}(m) > m$. E.g., $m=10$, $\text{structure}(10) = 106$.

The whole strategy could be called a unification of relational and categorical structures on a higher level of abstraction than relational and categorical notions. Instead of a lower level of “generalized morphisms” (Pfalzgraf) or the topological structures of n-categories.

Again, modern strategies of defending paradigmatic fundamentalism

As developed and argued at length at many places, polycontextural notions, theories and formalisms are not fibered theories, logics and semiotics, etc. (Pfalzgraf 1988), "Polycontextural systems are topological fiberings of monocontextural systems" (Toth 2009), simply because fibering, in all its forms, is based on non-fibered category theory and predicate logic of a single universe.
Toth, Light, 2009:

It might sound more trendy to use fiber-terminology and techniques instead of clumsy many-sorted logical theories with identity (Goguen 1981), both are nevertheless fundamentally rooted in the uniqueness of a universe (of discourse, objects, elements, individuals, signs, marks, etc.) and there is no paradigmatic insight or strategy to abandon this kind of fundamentalism in favor of pluri-verses disseminated over kenomic matrixes in the sense of polycontextural and kenogrammatic endeavors and risks.

If there is something like a polycontextural category theory - with diamond structure or not - then there exists equally a polycontextural distribution of fibered and many-sorted theories as there exists, since at least 1978, a polycontextural dissemination of multivalued logics.

5.2. Dissemination between lines, stars, circles and flags
5.2.1. Skeletal structures

Arboreal patterns, linear and star-patterns (without root) are skeletal structures for the architectonics of dissemination.
A tabular and matrix approach to disseminated categories opens up a quite natural semantical interpretation of non-transitive mediated categorical systems.

Table of skeletal structures

A valuation of skeletal structures with the key distinctions of categories, like domain and codomain of morphisms, is enabling a distribution of categories over all possible combinatorial constellations. It is proposed that the skeletal structure of classical category theory is given by the skeletal line-structure with complexity $m=3$.

Skeletal structures are not rooted. For the purpose of modeling line- and star-structures for distributed categories the directionality of rooted graphs might be first omitted. That is, only one direction for arrows as interpreted graphs is chosen. For cyclic graphs, right and left orientations of graphs have to be involved. Questions of knots are not yet treated properly.

Hence, from the possibilities of the graph $\mathbf{(3)} = (\bullet-\cdots-\bullet)$ and its arrow interpretation and its domain/codomain valuation, only the standard linear structure is considered as an architectonic base for category theory:

$$\text{val} \_{\text{arrow}}(\bullet-\cdots-\bullet)$$

That is, from $\text{val} \_{\text{dom/cod}}(\bullet-\cdots-\bullet)$ only the linear order

$$\begin{pmatrix}
\text{dom}_1 \\
\text{cod}_1
\end{pmatrix}
\text{with commutativity}
\begin{pmatrix}
\text{dom}_1 & \text{dom}_3 \\
\text{cod}_1 & \text{cod}_3
\end{pmatrix}
\text{is considered.}
$$

Both, left- and right-ordered linear structures, $(\bullet \rightarrow \cdots \bullet)$ and $(\bullet \leftarrow \cdots \bullet)$, are considered as isomorphic. Also, left- and right-ordered star structures, $(\bullet \rightarrow \cdots \bullet)$ and $(\bullet \leftarrow \cdots \bullet)$, are considered as isomorphic. Furthermore, linear and star structures coincide for $m=3$.

General procedure

$$\text{val(\text{graph})} = \text{distr(\text{matrix})}$$

architect: $\{\text{dom}_i, \text{cod}_i, i \in \mathbb{N}\} \rightarrow [\text{distribution - matrix}]$
Example

\[ \text{val}(\rightarrow \rightarrow) = \begin{bmatrix} \circ & \circ \\ \circ & \circ \\ \circ & \circ \end{bmatrix} \]

\[ \text{architect}(\rightarrow \rightarrow) = \begin{bmatrix} \text{dom}_1 & \text{dom}_2 \\ \text{cod}_1 & \text{cod}_2 \\ \text{dom}_2 & \text{cod}_2 \end{bmatrix}. \]

5.2.2. Line, star, cycles and flags

**Line**:

\[ \text{architect}_{\text{line}} = \begin{bmatrix} \text{dom}_1 & - \\ \text{cod}_1 & \text{dom}_2 \\ - & \text{cod}_3 \end{bmatrix} \]

\[ \text{MC}_{\text{line}} = \{ \text{cod}_1 \neq \text{dom}_2 \} \]

Hence, \( \text{Cat}_{\text{line}} = \begin{bmatrix} \text{dom}_1 & - & \text{dom}_3 \\ \text{cod}_1 & \text{dom}_2 & - \\ - & \text{cod}_2 & \text{cod}_3 \end{bmatrix} \)

\[ \text{Cat}_{\text{line}}(\text{hom}): \text{hom}(x, y) + \text{hom}(y, z) \Rightarrow \text{hom}(x, z). \]

**Star**:

\[ \text{architect}_{\text{star}} = \begin{bmatrix} \text{dom}_1 & - \\ \text{cod}_1 & \text{cod}_2 \\ - & \text{dom}_2 \end{bmatrix} \]

\[ \text{MC}_{\text{star}} = \{ \text{cod}_1 \neq \text{cod}_2 \} \]

\[ \text{Cat}_{\text{star}} = \begin{bmatrix} \text{dom}_1 & - & \text{dom}_3 \\ \text{cod}_1 & \text{ cod}_2 & - \\ - & \text{dom}_2 & \text{cod}_3 \end{bmatrix} \text{ or } \begin{bmatrix} \text{dom}_1 & - \\ \text{cod}_1 & \text{cod}_2 & - \\ - & \text{dom}_2 & \text{dom}_3 \end{bmatrix} \]

\[ \text{Cat}_{\text{star}}(\text{hom}): \text{hom}(x, y) + \text{hom}(x, z) \Rightarrow \text{hom}(x, z) \lor \text{hom}(z, x). \]

\[ \Rightarrow \text{Cat}_{\text{line}} \neq \text{Cat}_{\text{star}}. \]

**Star**:
\[ \text{architect}_{\text{ster}}(4) = \begin{pmatrix} \text{dom}_1 & - & - & - \\ \text{cod}_1 & \text{dom}_2 & \text{dom}_3 & - \\ - & \text{cod}_2 & - & - \\ - & - & \text{cod}_3 & - \end{pmatrix} \]

\[ \text{MC}_{\text{ster}}(4) = \{ \text{cod}_1 \neq \text{dom}_2 = \text{dom}_3 \} \]

Hence, \( \text{Cat}_{\text{ster}}(4) = \begin{pmatrix} \text{dom}_1 & - & - & - & - & - \\ \text{cod}_1 & \text{dom}_2 & \text{dom}_3 & - & - & - \\ - & \text{cod}_2 & - & \text{dom}_4 & \text{cod}_4 & - \\ - & - & \text{cod}_5 & \text{cod}_4 & - & \text{cod}_5 \end{pmatrix} \)

\[ \text{Cat}_{\text{ster}}(\text{hom}) = \left\{ \begin{array}{l} \text{hom}(x, y) \circ \text{hom}(y, z) \Rightarrow \text{hom}(x, z) \\ \text{hom}(x, y) \circ \text{hom}(y, v) \Rightarrow \text{hom}(x, v) \\ \text{hom}(y, z) \circ \text{hom}(z, v) \Rightarrow \text{hom}(y, v) \end{array} \right\} \]

\text{Line}(4):

\[ \text{architect}_{\text{line}}(4) = \begin{pmatrix} \text{dom}_1 & - & - \\ \text{cod}_1 & \text{dom}_2 & - \\ - & \text{cod}_2 & \text{dom}_3 \\ - & - & \text{cod}_3 \end{pmatrix} \]

\[ \text{MC}_{\text{line}}(4) = \{ \text{cod}_1 \neq \text{dom}_2, \text{cod}_2 \neq \text{dom}_3 \} \]

\[ \text{Cat}_{\text{line}}(4) = \begin{pmatrix} \text{dom}_1 & - & - & - & \circ & \circ \\ \text{cod}_1 & \text{dom}_2 & - & \circ & \circ & \circ \\ - & \text{cod}_2 & - & \text{dom}_3 & \circ & \circ \\ - & - & \text{cod}_3 & - & \circ & \circ \end{pmatrix} \]

\[ \text{Cat}_{\text{line}}(\text{hom}) = \left\{ \begin{array}{l} \text{hom}(x, y) \circ \text{hom}(y, z) \circ \text{hom}(z, v) \Rightarrow \text{hom}(x, v) \\ \text{hom}(x, y) \circ \text{hom}(y, z) \Rightarrow \text{hom}(x, z) \\ \text{hom}(y, z) \circ \text{hom}(z, v) \Rightarrow \text{hom}(y, v) \end{array} \right\} \Rightarrow \text{hom}(x, v) \]

\[ \Rightarrow \text{Cat}_{\text{line}}(4) \neq \text{Cat}_{\text{ster}}(4) \]
\textbf{Star–line}^{(s)}:

\begin{equation*}
\text{architecture}^{(s)}_{\text{star-line}} = \begin{pmatrix}
\text{dom}_1 & \text{cod}_1 \\
\text{dom}_2 & \text{dom}_3 \\
\text{dom}_4 & \text{dom}_5 \\
\text{cod}_2 & \text{dom}_6 \\
\text{cod}_3 & \text{cod}_4 \\
\text{cod}_4 & \text{cod}_5 \\
\end{pmatrix}
\end{equation*}

\begin{equation*}
\text{MC}_{\text{star-line}} = \{\text{cod}_1 \neq \text{dom}_2 \neq \text{dom}_3, \text{cod}_2 \neq \text{dom}_4\}
\end{equation*}

\text{Null}

\begin{equation*}
\text{Cal}^{(s)}_{\text{star-line}} = \begin{pmatrix}
\text{dom}_1 & \text{dom}_2 & \text{dom}_3 & \text{dom}_5 & \text{dom}_7 & \text{dom}_9 & \text{dom}_{10} \\
\text{cod}_1 & \text{dom}_4 & \text{cod}_5 & \text{dom}_6 & \text{cod}_7 & \text{cod}_8 & \text{dom}_4 \\
\end{pmatrix}
\end{equation*}

\textbf{Cycle}^{(s)}:

\begin{equation*}
\text{architecture}^{(s)}_{\text{left-cycle}} = \begin{pmatrix}
\text{dom}_1 & \text{cod}_2 & \text{dom}_4 \\
\text{cod}_1 & \text{dom}_3 & \text{cod}_4 \\
\text{dom}_2 & \text{cod}_3 & \text{dom}_4 \\
\end{pmatrix}
\end{equation*}

\begin{equation*}
\text{architecture}^{(s)}_{\text{right-cycle}} = \begin{pmatrix}
\text{dom}_1 & \text{cod}_2 & \text{cod}_3 \\
\text{cod}_1 & \text{dom}_2 & \text{dom}_3 \\
\text{ cod}_2 & \text{cod}_3 & \text{dom}_4 \\
\end{pmatrix}
\end{equation*}

\begin{equation*}
\text{architecture}^{(s)}_{\text{left-cycle}} \neq \text{architecture}^{(s)}_{\text{right-cycle}}
\end{equation*}
Flag

\[
\text{architect}^{(b)}_{\text{right-cycle-flag}} = \begin{pmatrix}
\text{dom}_1 & - & - & \text{cod}_4 & - \\
\text{cod}_1 & \text{dom}_2 & - & - & - \\
- & \text{cod}_2 & \text{dom}_3 & - & - \\
- & - & \text{cod}_3 & \text{dom}_4 & - \\
- & - & - & \text{dom}_5 & \text{cod}_5 \\
\end{pmatrix}
\]

\[
\text{right-cycle-flag} \quad E \\
\uparrow \\
A \rightarrow B \rightarrow C \rightarrow D \rightarrow A
\]

architect^{(c)}_{\text{right-cycle-flag}} = architect^{(b)}_{\text{right-cycle-flag}}

Diamond — Star

\[
\text{architect}^{(c)}_{\text{star}} = \begin{pmatrix}
\text{dom}_1 & - & - \\
\text{cod}_1 & \text{dom}_2 & \text{dom}_3 \\
- & \text{cod}_2 & - \\
- & - & \text{cod}_3 \\
\end{pmatrix} \Rightarrow \left( A \rightarrow B \circ \left( B \rightarrow C \right) \right)
\]

Diamond — Star — Rule

\[
\begin{align*}
A \rightarrow B \circ \left( B \rightarrow C \right) \\
A \rightarrow B \circ \left( B \rightarrow D \right)
\end{align*}
\]

Star — rules

\[
\begin{align*}
A \rightarrow B \circ \left( B \rightarrow C \right) \\
A \rightarrow C \\
A \rightarrow D \\
C \rightarrow D
\end{align*}
\]
Birkhoff arithmetics

Example

$$\text{architect}_{\text{stor-in}_0}^{(3)} = \text{architect}_{\text{stor}}^{(4)} \oplus \text{architect}_{\text{view}}^{(2)} :$$

\[
\begin{pmatrix}
\text{dom}_1 & - & - \\
\text{cod}_1 & \text{dom}_2 & \text{dom}_3 \\
- & \text{cod}_2 & - \\
- & - & \text{cod}_3
\end{pmatrix}
\oplus
\begin{pmatrix}
\text{dom}_1 \\
\text{cod}_1 \\
- \\
- \\
- \\

\end{pmatrix}
Elements of Diamond Set Theory

Some more parts of the mosaic towards semiotics, logic, arithmetic and category theory

Rudolf Kaehr Dr.@
ThinkArt Lab Glasgow

Abstract

Further elements are sketched towards an interplay of polycontextural logic, semiotics, arithmetic and set theory. Basics for junctional and transjunctional quantification in polycontextural logic are presented. Hints to metamorphic changes between sets, classes and conglomerates in pluri-verses are given.

1. Diamond set theory

1.1. Sets, universes, conglomerations

It is said that category theory is a departure from set theory, other are more radical and insists that category theory has nothing to do with set theory at all. From a foundational point of view, Herrlich makes it clear that a proper mathematical formalization of categories needs different sorts of collections of different generality. He distinguishes sets, classes and conglomerates as the collections of a universe appropriate to deal with categories. Nevertheless, there is no special conflict necessary between set theory and category theory. Both are based on different, even complementary, thematizations of formal thinking. And as such, both are using mutually methods from each other. And both are, logically and semiotically, if blindness is not dominating, based on common grounds.

Collections of the universe $U = \{\text{sets, classes, conglomerates}\}$.

The objects of category theory belong to these collections. Obviously, categorical objects are not simply sets but, e.g., categories of categories, hence surpassing all reasonable, i.e., contradiction-free notions of set theory. Hence, “One universe as a foundation of category theory”, (Mac Lane, 1969)

Diamond theory is in no way less general than category theory, but the objects of diamonds are not only collections of different degrees of abstractions, but are bi-objects from their very beginning. Bi-objects are complementary objects constructed as an interplay between acceptional and rejectional aspects of diamond theory.

Hence the objects of diamonds are not simply belonging to the universe $U$ of conglomerates with its classes and sets, but to the 2-verse (di-verse) as a complementarity of the universe of acceptional and the "universe" of rejectional objects.

Category theory happens in a universe, polycontexturality in a pluri-verse and diamond theory in a di-verse $2-U$ of complementarity.

Thus, $2-U = \{\text{collections } || \text{ collections}\}$.

Hence, $2-U = \{(\text{set}||\text{set}), (\text{class}||\text{class}), (\text{conglomerate}||\text{conglomerate})\}$. 

1 of 18

25/3/09 4:45 pm
A di-verse conception of collections opens up the possibility of metamorphic chiasms between their constituents [set, class, conglomerate].

This happens in a similar way like in polycontexturally disseminated categories. That is, a set in one contexture can be seen as a class in another contexture, etc. This happens on the base of as-abstractions. In category theory "a set is a set, a class is a class and a conglomerate is a conglomerate"; and nothing else happens. The hierarchy is strict and well defined. The notions, set, class, conglomerate, are defined by the is-abstraction.

This is different for polycontextural systems but also for diamond theory. For both, collections are still well defined and placed in their hierarchy. But because of the multitude of universes, interactions are possible between different kinds of collections. These interactions are strictly defined, too. They are ruled by the mechanism of chiastic metamorphosis.

Obviously, to describe the rules of sets, classes and conglomerates in di-verses we need some knowledge from diamond theory, which is based then just on such rules. That is, the whole idea of a di-verse is based on conceptions of diamond theory.

In diamond theory, conglomerates are not covering the situations of bi-objects. Bi-objects are polycontextural, thus they are members of disseminated conglomerates.

Contexture(Conglomerate(Class(Set)))

On the base of other conceptualizations of the diamond way of thematization, a transition from 2-verses to n-verses is not excluded. This should not be confused with the general multi-verses of polycontextural systems.

1.2. Diamond strategies for bi-objects

Bi-objects are strictly divided into a saltatorial and a categorical part. With the interplay and interactivity between categories and saltatories, ruled by the bridging conditions and operations, a new type of object emerges: bi-objects with mixed parts. Hence, diamonds are involved not simply in bi-objects but in bridges, too.

Bridges are composed by difference operation into a combination of categorical and saltatorial parts. In this sense, they are the both-at-once aspect of diamond bi-objects. A change of perspective in favor to the bridging operation as such, abstracting from its bi-objects, the neither-nor structure of bi-objects might be constructed.

Hence, we have to distinguish 4 aspects of diamonds: categorical, saltatorial, interplay (bridging as a mix) and interactionality (bridging as such).

1.3. Elements of a diamond theory of conglomerates

Both approaches, the polycontextual approach to logic and diamond theory as well the approach of mathematical semiotics, is first and mainly considered of abstract cognitive and volitive structures and transformations. Propositions about elements of the semiotic, polycontextual and diamond theoretical domains are not yet proposed in a formal and formalized way. Like classical propositional logic is enhanced by a theory of quantification, which allows to state statements about elements, properties and quantifications with all (∀), some (∃), exactly one (∃!), the same shall be introduced for transclassical approaches to formal thinking.

In classical logic, the logic of predicates, i.e. first-order logic, is defined on the base of a single, uniform or structured, universe of individual elements or objects, transclassical logic has to be defined in concert with a plurality of domains, called pluri-verse. Diamond theory of pluriverses is reflecting the otherness of any thematized universe of a pluriversal "set" or "domain" theory.

Classical logic and set theory is restricted to structure its single universe into sorts, sub-domains, layers, levels etc. without touching the strict hierarchy between the single universe and its parts or subsystems.

Today, set theory is enlarged, for the reasons of category theoretical aims, to a theory of universes, conglomerates, large and small sets, i.e classes and sets.

Laws for sets
Laws for classes
Laws for conglomerates
Laws for universes
Universes are founded in uniqueness
Laws for chasms between universes.

*Metamorphic* interchanges between universes, conglomerates, classes and sets in a
polycontextural framework are the fundamental mechanisms of change.
Changes might be *iterative* or *accretive*.
Iterative changes happens in a stable framework, accretive changes are augmenting the
complexity of the framework.

This is not the place to enter into the intriguing world of mathematical foundations, its strategies
of avoiding paradoxes and extending the fields of mathematical reasoning.

One small hint should be recalled. There is no primary need to avoid paradoxes in polycontextural
theories because they are accessible to a paradox-free implementation based on the chiasm
between elements and predicates, or sets and elements. It was sketched in (Kaehr 1978), that
for each contexture, a contexture specific local paradox might be constructed and that the
system as such is not involved, globally, into the well known unavoidable paradoxes of
self-referentiality.

\[
\begin{align*}
\text{Chiasm}_{\text{iter}}(\text{Fluiverse}(x)) &= \text{Fluiverse}(x) \\
\text{Chiasm}_{\text{ac}}(\text{Fluiverse}(m)) &= \text{Fluiverse}(m+n)
\end{align*}
\]

![Diagram](https://example.com/diagram.png)

The hierarchy of “collections”

**Universe** = Conglomerates | Classes | Sets | Elements | after Herrlich

**Universal Category Theory** =

\[
\begin{align*}
\text{Universe} = & \text{Conglomerate} \\
\text{Class} = & \text{Set} \\
\{\text{Element}\} = & \text{Set}
\end{align*}
\]
### 1.3.1. Ontology

**General Set Theory (Boolos)**

"GST features a single primitive ontological notion, that of set, and a single ontological assumption, namely that all individuals in the universe of discourse (i.e., all mathematical objects) are sets. There is a single primitive binary relation, set membership; that set a is a member of set b is written a ∈ b (usually read "a is an element of b")." Wiki

1. **Axion of Extensionality:**
   The sets x and y are the same set if they have the same members.
   \[ \forall x \forall y [ \forall z (z \in x \leftrightarrow z \in y) \rightarrow x = y]. \]

2. **Axiom Schema of Specification**
Separation or Restricted Comprehension: If \( z \) is a set and \( \phi \) is any property which may be satisfied by all, some, or no elements of \( z \), then there exists a subset \( y \) of \( z \) containing just those elements \( x \) in \( z \) which satisfy the property \( \phi \).

\[
\forall z \exists y \forall x [x \in y \iff (x \in z \land \phi(x))].
\]

3. Axiom of Adjunction
If \( x \) and \( y \) are sets, then there exists a set \( w \), the adjunction of \( x \) and \( y \), whose members are just \( y \) and the members of \( x \).[1]

\[
\forall x \forall y \exists w \forall z [z \in w \iff (z \in x \lor z = y)].
\]

**General Diamond Set Theory**
GDST\(^{(m)}\) features for each contexture a single primitive contextual notion, that of bi-set, and for each a single contextual assumption, namely that all bi-individuals in the pluri-verse of thematizations (i.e., all mathematical objects) are bi-sets of complexity \( m \).

There is **locally** for each contexture of a polycontexturality a single primitive binary relation, bi-set membership; that set \((A,a)\) is a member of set \((B,b)\) is written \((A,a) \in (B,b)\) (usually read "a is an element of b").

There is **globally** for each constellation of contextures and uni-verses a chiastic exchange relation between contextures and uni-verses of the pluri-verse.

The logic of GDST\(^{(m)}\) is the polycontextural diamond logic PolyLogic\(^{(m, n)}\).

GST is derived from GDST by reducing pluri-verses to uni-verse, bi-sets to sets and by omitting chiasm.

Between the concept of "Urelement" and the concept of "Contexture" a duality holds. A Urelement is an element which might be a member of a set but it doesn't contain itself any members. A contexture isn't a member of a set but contains all sets of itself. In a chiastic scenario, a contexture might change its functionality into the functionality of an element of another contexture.

## 2. Quantification in polycontextural logics

First-order logic quantification is distributed over different contextual domains of polycontextural logic.

As for FOL, quantification in polylogics requires quantifiers which are applied to predicates and functions and their variables. And substitution is required too.

Quantification in polylogics is naturally realized by universal and existential quantification introduced in analogy to FOL for each contexture. Because of polycontexturality, additional to the separated actions of contextual quantifiers, quantifier for interactions between different contextures have to be introduced, i.e. transjunctural quantifiers.

For a 3-contextural logic Log\(^{(3)}\) universal and existential quantifiers are distributed over 3 places. In general, for \( m \) there are \( \binom{m}{2} \) places to consider.

Hence, the patterns are in correspondence to the distribution of propositional conjunctions and disjunctions.
Typical polycontextural quantifiers are the *transjunctural* quantifiers Q and G. Similar to the duality of logical quantifiers, ∀ and ∃, the transjunctural quantifiers Q and G are interchangeable.

Quantification is in analogy to propositional versions. That is,
\[ QQQ \equiv QGQ, \quad GGQ \equiv GGG. \]

Some propositional versions: "p" like Q, "q" like G:
\[ p \equiv q, \quad \neg p \equiv \neg q. \]
\[ \neg \neg p \equiv p, \quad \neg \neg \neg p \equiv \neg \neg p. \]
\[ p \equiv \neg q, \quad \neg p \equiv q. \]

Transjunctural quantifiers

\[ QQQ, \quad GGQ, \quad G \forall Q, \quad Q \forall Q, \quad \forall Q, \quad Q \exists Q, \quad Q \exists Q, \quad \exists \exists Q, \quad \exists \exists Q. \]

Models

\[ Q \exists \forall x(\exists p(\exists x) \equiv P(\exists x) \land \forall \neg \exists P(\exists x) \land \exists \exists P(\exists x)) \land \ldots \land \exists \exists P(\exists x). \]

Om \[ k^{(3)} \equiv \cup^{(3)} \]

Wording for first-Order Logic:

"The domain D is a set of "objects" of some kind. Intuitively, a first-order formula is a statement about objects; for example, \( \exists x.P(x) \) states the existence of an object x such that the predicate P is true where referred to it. The domain is the set of considered objects. As an example, one can take D to be the set of integer numbers." (WiKi)

Because first-order logic objects are obviously characterized by a single domain (universe, contexture), the domain of polycontextural quantification is not a single universal set of objects but, metaphorically, a poly-set of relations.

An interesting example for "poly-sets of relations" is given by the system of triadic-trichotomic sign relations. An adequate thematization, modeling and logification of triadic-trichotomic domains, like Peircean semiotics, needs a structurally adequate logical apparatus. First-order logic is reducing such complex structures to
mono-contextural predicative objects.

### 2.1. Tableau rules for polycontextural quantifiers

#### 2.1.1. Syntactic schemes
2.1.2. Tableaux rules for \((Q \exists \forall)\)

Relation \(R = (P_1^1, P_1^2)\) is a dual-predicate over the polycontextual tuple \((x_1^3, x_2^3)\).

\[
\begin{align*}
\frac{(P_1^1, P_1^2) \times (P_2^3) \times (P_3^3)}{(P_1^1 \times P_1^2) \times P_2^3 \times P_3^3} \\
\frac{(P_1^1 \times P_1^2) \times P_2^3 \times P_3^3}{(P_1^1 \times P_1^2) \times P_2^3 \times P_3^3} \\
\frac{(P_1^1 \times P_1^2) \times P_2^3 \times P_3^3}{(P_1^1 \times P_1^2) \times P_2^3 \times P_3^3}
\end{align*}
\]
For all junctional quantificators there exists a quantificational representation with single objects \( a \).

For all transjunctional quantificators there exists a quantificational representation with transcontextural tupels \((a, b)\).

Objectivity and Objectionality

The objectivity of an object in First-Order Logic and set theory is characterized by its
ontology of *individual* and *predicate*, i.e. substance and attribute. There is a strict hierarchic order between individuals and predicates. Objectivity is excluding, logically and ontologically, self-referential statements between individuals and predicates, i.e. a predicate can not change into an individual and vice versa without producing in its logical framework a contradiction.

*Objectionality* of a polycontextural object depends on the complexity of the interplay between entities and characteristics of different contexts. (Kaehr, Materialien 1976, Siemens-Studie, 1985)

**Linguistic example**

A 3-contextural object $O^{(3)}$ like a (contexturally) complementary object *waveparcel* (Heisenberg) has the property $P^{(3)}$ with locally $P^1$ for the wave and for the *parcel* $O^2$ the property $P^2$ and globally the property $P^3$ for the composed notion of wave and parcel, $O^3$, *waveparcel*.

Quantification happens intra-contexturally for all contexts by the junctional quantifiers $\forall$ and $\exists$.

Quantification between different contexts, focusing different contexts at once, happens with transjunctional quantifiers, e.g. $Q$ and $G$.

**Famous application to Russell’s devilish construction, but escaping paradox**

1. $\exists \alpha \exists \beta \exists \gamma \forall \delta (\forall \epsilon \delta (\epsilon \in \alpha \land \delta \in \beta \land \gamma \in \epsilon))$
   
   postulation of constellation

2. $\forall \gamma \delta \in \beta (\forall \epsilon \delta \in \gamma \land \epsilon \in \beta)$
   
   specification - contextural selection

3. $\forall \gamma \delta \alpha \in \beta (\forall \epsilon \delta \in \gamma \land \epsilon \in \beta ^{\gamma})$
   
   accretive substitution $Q$

4. $\forall \gamma \delta \exists \alpha \in \beta (\forall \epsilon \delta \in \gamma \land \epsilon \in \beta ^{\gamma})$
   
   comparison: non-contradiction

**Strategy:** chiasm $\{ \forall, \exists, \alpha, \beta, \gamma \}$

### 2.1.3. Mimicking General Set Theory (GST)

GST:

1. $\forall x \forall y \exists z (x \in z \iff x = y)$

2. $\exists z \exists y (x = y \iff (x \in z \land y \in z))$

3. $\forall x \forall y \forall z (x \in z \iff (z \in y \land z \in x \land z \in y))$

**Axioms of Extensionality for 3-contextural set theory GST$^{(3)}$**

**Homogeneous extensionality**

1. $\forall \alpha \forall \beta \forall \gamma \forall \delta (\forall \epsilon \epsilon \in \alpha \land \epsilon \in \beta \land \epsilon \in \gamma \land \epsilon \in \delta)$

2. $\forall \alpha \forall \beta \forall \gamma \forall \delta (\forall \epsilon \epsilon \in \alpha \land \epsilon \in \beta \land \epsilon \in \gamma \land \epsilon \in \delta)$

3. $\forall \alpha \forall \beta \forall \gamma \forall \delta (\forall \epsilon \epsilon \in \alpha \land \epsilon \in \beta \land \epsilon \in \gamma \land \epsilon \in \delta)$

4. $\forall \alpha \forall \beta \forall \gamma \forall \delta (\forall \epsilon \epsilon \in \alpha \land \epsilon \in \beta \land \epsilon \in \gamma \land \epsilon \in \delta)$
### 2.2. Polylogical quantification rules

#### 2.2.1. DeMorgan rules

**Dual-Cycle**

\[ \forall \forall \exists \iff [\text{dual}_1] \quad \exists \forall \exists \iff [\text{dual}_2] \quad \forall \exists \exists \iff [\text{dual}_2] \]

**II. Dual-Cycle**

\[ \forall \forall \exists \iff [\text{dual}_{1,2}] \quad \exists \exists \forall \iff [\text{dual}_{1,2}] \]

*Kaehr, Materialien, 1978*

More brackets at:
ConTextures. Programming Dynamic Complexity.
http://www.thinkartlab.com/pkl/lola/ConTeXtures.pdf
2.2.2. Distribution rule for transjunctional quantifiers

Propositional distribution rule

\[
\begin{align*}
\alpha \text{ simul } \beta &\text{ et } \beta \text{ simul } \gamma \Rightarrow \\
\alpha \text{ et } \beta &\text{ simul } (\beta \text{ et } \gamma)
\end{align*}\
\]

Example of a 3 element domain quantificational rule: \(\equiv \text{ simul = simultaneous}\)

\[
\begin{align*}
\forall x \exists y \forall z \big( (P^1 \text{ et } F^1 \text{ si } F^2) \text{ et } (P^1 \text{ si } F^2) \text{ et } (P^2 \text{ et } F^2) \text{ si } P^2 \text{ et } F^2) &\big)\\
\big( (F^1 \text{ et } F^2) \text{ et } (F^1 \text{ et } F^2) \text{ si } (F^2 \text{ et } F^2) \text{ et } (F^2 \text{ et } F^2) \big)
\end{align*}\
\]
2.3. Quantification for diamond theory

2.3.1. 3-Contextural diamond

Scheme for diamond – quantification (reduced)

\[ \{ \begin{array}{c}
S_1 \\
S_2 \\
S_3 \\
S_4 \\
\end{array} \} = \left[ \begin{array}{c}
S_1 \\
S_2 \\
S_3 \\
\end{array} \right] \quad \text{with } S \in \{ \forall, \exists, \pi, \varphi \} \\
\]

\[ \{ \begin{array}{c}
Q_1 \exists_2 \forall_3 \exists_4 \\
\end{array} \} = \left[ \begin{array}{c}
Q_1 \\
\exists_2 \\
\forall_3 \\
\exists_4 \\
\end{array} \right] \]

Example of a diamond – quantificational formula

\[ \left( \begin{array}{c}
Q_1 \\
\exists_2 \\
\forall_3 \\
\exists_4 \\
\end{array} \right) \left( \begin{array}{c}
x_1 \\
x_2 \\
x_3 \\
\end{array} \right) \left( \begin{array}{c}
\pi_6 \\
\pi_5 \\
\pi_3 \\
\end{array} \right) \]

quantors | variables | predicates | variables

\[ \left( \begin{array}{c}
\pi_6 \\
\pi_5 \\
\pi_3 \\
\end{array} \right) \left( \begin{array}{c}
x_1 \\
x_2 \\
x_3 \\
\end{array} \right) \left( \begin{array}{c}
\pi_6 \\
\pi_5 \\
\pi_3 \\
\end{array} \right) \]

Duality for diamond – quantificational formulas
\[
\text{dual}_1 \left( \text{dual}_2 \left( \text{dual}_1 \left( D(x) \right) \right) \right) = \\
\begin{bmatrix}
S_1 \\
S_2 \\
S_3
\end{bmatrix} \xrightarrow{\text{dual}_1} \\
\begin{bmatrix}
S_1 \\
S_2 \\
S_3
\end{bmatrix} \xrightarrow{\text{dual}_2} \\
\begin{bmatrix}
S_1 \\
S_2 \\
S_3
\end{bmatrix} \xrightarrow{\text{dual}_1} \\
\begin{bmatrix}
S_1 \\
S_2 \\
S_3
\end{bmatrix}
\]

\[
\text{dual}_2 \left( \text{dual}_1 \left( \text{dual}_2 \left( D(x) \right) \right) \right) = \\
\begin{bmatrix}
S_4 \\
S_5 \\
S_6
\end{bmatrix} \xrightarrow{\text{dual}_2} \\
\begin{bmatrix}
S_4 \\
S_5 \\
S_6
\end{bmatrix} \xrightarrow{\text{dual}_1} \\
\begin{bmatrix}
S_4 \\
S_5 \\
S_6
\end{bmatrix} \xrightarrow{\text{dual}_2} \\
\begin{bmatrix}
S_4 \\
S_5 \\
S_6
\end{bmatrix}
\]

Hence, cycle \( z \): \( \text{dual}_1 \left( \text{dual}_2 \left( \text{dual}_1 \left( D(x) \right) \right) \right) = \text{dual}_2 \left( \text{dual}_1 \left( \text{dual}_2 \left( D(x) \right) \right) \right) \).

**Example:** Tableaux rules for \( (Q, \exists_2 \forall_3 \exists_4) \)

\[
\begin{bmatrix}
\exists_4 \\
\forall_3 \\
\exists_2
\end{bmatrix}
\]

\[
\begin{array}{c}
f_4 \left( \exists_4 \forall_3 \exists_4 \right) \times \left( \forall_3 \exists_4 \right) \\
\begin{bmatrix}
Q_1 \\
S_1 \\
S_5
\end{bmatrix} \times \left( \forall_3 \exists_4 \right)
\end{array}
\]

\[
\begin{array}{c}
t_4 \left( \exists_4 \forall_3 \exists_4 \right) \times \left( \forall_3 \exists_4 \right) \\
\begin{bmatrix}
Q_1 \\
S_1 \\
S_5
\end{bmatrix} \times \left( \forall_3 \exists_4 \right)
\end{array}
\]

\[
\begin{array}{c}
t_4 \left( \exists_4 \forall_3 \exists_4 \right) \times \left( \forall_3 \exists_4 \right) \\
\begin{bmatrix}
Q_1 \\
S_1 \\
S_5
\end{bmatrix} \times \left( \forall_3 \exists_4 \right)
\end{array}
\]

\[
\begin{array}{c}
t_4 \left( \exists_4 \forall_3 \exists_4 \right) \times \left( \forall_3 \exists_4 \right) \\
\begin{bmatrix}
Q_1 \\
S_1 \\
S_5
\end{bmatrix} \times \left( \forall_3 \exists_4 \right)
\end{array}
\]

\[
\begin{array}{c}
t_4 \left( \exists_4 \forall_3 \exists_4 \right) \times \left( \forall_3 \exists_4 \right) \\
\begin{bmatrix}
Q_1 \\
S_1 \\
S_5
\end{bmatrix} \times \left( \forall_3 \exists_4 \right)
\end{array}
\]

\[
\begin{array}{c}
t_4 \left( \exists_4 \forall_3 \exists_4 \right) \times \left( \forall_3 \exists_4 \right) \\
\begin{bmatrix}
Q_1 \\
S_1 \\
S_5
\end{bmatrix} \times \left( \forall_3 \exists_4 \right)
\end{array}
\]

\[
\begin{array}{c}
t_4 \left( \exists_4 \forall_3 \exists_4 \right) \times \left( \forall_3 \exists_4 \right) \\
\begin{bmatrix}
Q_1 \\
S_1 \\
S_5
\end{bmatrix} \times \left( \forall_3 \exists_4 \right)
\end{array}
\]

**2.3.2. 4-contextural diamond**
2.4. Smullyan unification for diamond quantification

2.4.1. Smullyan’s unification rules for “propositional” constellations

PolyLogics
Towards a formalization of polycontextural Logics.
http://www.thinkartlab.com/pkl/lola/PolyLogics.pdf

From Dialogues to Polylogues

Place-valued logics around Cybernetic Ontology, the BCL and AFOSR
http://www.thinkartlab.com/pkl/lola/AFOSR-Place-Valued-Logic.pdf

2.4.2. Smullyan’s unification rules for “quantificational” constellations

3. Interplay of semiotics, logics, set theory and arithmetic

3.1. Strategy

A study of polycontextural semiotics, focused on semiotics alone, is not yet guaranteeing its polycontexturality. The logical, arithmetical and set theoretical status of semiotics, mono- and polycontextural, remains undetermined if its corresponding logics, arithmetic and set theory (incl. category theory) are not determined and explicitly developed as polycontextural systems.
On the other hand, what value would have a semiotic system without any chances to proof statements, studying its arithmetical, set and category theoretical properties? Until now, arithmetic, e.g., in semiotics, is not recognizing semiotical complexity but is calculating some combinatorial properties which are independent of the genuine, say triadic-trichotomous structure. Similar mismatches happens with well known inadequate combinatorial studies of morpho- and kenogrammatics.

The same situation has to be recognized for other formal systems. A formalization of polycontextural logic is easily reduced to monocontexturality by arithmetization (Gödelization) if there is not at the same time a polycontextural arithmetic at hand to defend the strategies of polycontextural logic. And obviously, because there is no initial origin, the carousel has to go through all stations of logic, arithmetic, semiotic, category and set theory, thematization, meta- and protolanguage, etc. to deliver and interplaying foundation for each other.

Proto- and meta-language of formal systems, as normed natural languages, are important to rule the relation between natural and formal languages, especially in the case of the interpretation of formal terms for philosophical or applicative aims. If proto-language-based considerations are limiting the formal possibilities of formal constructions, the reasons for the restrictional decision should be made as explicit as possible. Also should formal possibilities be accepted which haven’t yet found an interpretation.

Earlier on, there was a big philosophical topic to fight against the advent of traditional many-valued logic with the argument that the natural meta-language used to motivate and to develop many-valuedness is a priori two-valued. Hence, there is no escape from the two-valuedness of human thinking with the help of many-valued logic. Today, not even the question is recognized.

3.2. Sketch

For the purpose of recent introductory sketches of a descriptive characterization of the idea of poly-semiotics, it might be sufficient to hint to the decision to use 3-contextural subsystems of 4-contextural logics and arithmetics. Instead of the usual decomposition into elementary contextures.

Hence, from a 4-contextural logic, \( \text{Log}^{(4)} \), with its six 2-contextures, \( \text{Log}^{(4,2)} \), its four 3-contextures, \( \text{Log}^{(4,3)} \), only the four 3-contextural subsystems are in direct correspondence to the 4-contextural (poly)semiotics, decomposed into its 3-contextural semiotic parts. The same holds in general for the interplay between arithmetic, set theory and semiotics.

\[
\text{Graphematics}^{(4,3,2)} = \left( \text{Sem}^{(4,2)}, \text{Log}^{(4,2)}, \text{Arith}^{(4,2)}, \text{Set}^{(4,2)} \right)
\]

with

\[
\text{Sem}^{(4,2)} = \left( \text{Sem}^{(3,2)}, \text{Sem}^{(2,2)}, \text{Sem}^{(3,3)}, \text{Sem}^{(3,4)} \right)
\]

\[
\text{Log}^{(4,2)} = \left( \text{Log}^{(3,1)}, \text{Log}^{(3,2)}, \text{Log}^{(3,3)}, \text{Log}^{(3,4)} \right)
\]

\[
\text{Arith}^{(4,2)} = \left( \text{Arith}^{(3,1)}, \text{Arith}^{(3,2)}, \text{Arith}^{(3,3)}, \text{Arith}^{(3,4)} \right)
\]

\[
\text{Set}^{(4,2)} = \left( \text{Set}^{(3,1)}, \text{Set}^{(3,2)}, \text{Set}^{(3,3)}, \text{Set}^{(3,4)} \right)
\]

\( \text{Sem}^{(4,2)} \) is a 4-contextural semiotics, which is realizing the paradigmatic and conceptual transformations of the 4-contextural logics \( \text{Log}^{(4)} \), set theory \( \text{Set}^{(4)} \) and arithmetic \( \text{Arith}^{(4)} \).
$\text{Log}^{(4,2)}$ is a 4-contextual logic, which is realizing the structural and deductional transformations of the 4-contextural semiotics Sem $^{(4)}$, set theory $\text{Set}^{(4)}$ and arithmetic $\text{Arith}^{(4,2)}$.

$\text{Arith}^{(4,2)}$ is a 4-contextual arithmetic, which is realizing the structural and computational transformations of the 4-contextural semiotics Sem $^{(4)}$, set theory $\text{Set}^{(4)}$ and logics $\text{Log}^{(4,2)}$.

$\text{Set}^{(4,2)}$ is a 4-contextual set theory, which is realizing the objectional and predicational transformations of the 4-contextural semiotics Sem $^{(4)}$, arithmetic $\text{Arith}^{(4)}$ and logics $\text{Log}^{(4,2)}$.

$\text{Graphematics}^{(4,3,2)}$ is the interplay of semiotics, logics, set and category theory and arithmetic of complexity $\text{compl}^{(4,2)}$. 
Interactional operators in diamond semiotics

From polylogical transjunctions to polysemiotic interactions and reflections

Rudolf Kaehr Dr.@
ThinkArt Lab Glasgow

Abstract
Comparing polycontextural logics and semiotics, the idea of interactionality is introduced as a further step of interaction in embedded semiotics. To achieve interactionality/reflectionality for semiotics some new concepts had been introduced. For polylogical systems, transjunctional operators are defining interactions between logics. After a sketch of polysemiotics, poly-semiotic formulations of interaction and reflection operators are introduced.

1. Semiotics and polylogics

1.1. Motivation
Transjunction, as important operators of interaction, are well known in polycontextural logics. Semiotics offers a different approach to cognitive/volitive modeling. In this paper, some steps to sketch an interactional approach in semiotics along the experiences, models and formalizations of polycontextural logic, is undertaken.1

The semiotic matrix is introduced as the “Cartesian product” of sub-signs (Bense, Toth).

<p>| | | | |</p>

<td>3.1</td>
<td>3.2</td>
<td>3.3</td>
</tr>
</tbody>
</table>

“A sub-sign is obtained by mapping the three sign relations (.1, .2, .3) into themselves.”

“The rows are called triadic values and the colomns trichotomic values of the matrix. In order to build a a sign class, one sub-sign has to be taken out of each of the three rows, the rows thus being different.”

“Therefore, sign sets like *(3.1 3.2 1.3), *(2.1 2.2 1.2), *(1.1 1.3 3.1) are not considered sign classes.” (Toth, Ghost, p.9)

Cartesian products as a conceptual point of contact.2
The aim of polycontextural semiotics is to design a dynamic sign theory without any fixation on a special or privileged n-ary and m-adic system. Another attempt to augment the structural and architectonic flexibility of semiotics is proposed by Toth’s approach to a 3- and 4-dimensional semiotics resulting in complex topological structures. (Cf. Transit-Korridor, 2009)
1.2. Is there a privileged number for dissemination?

An introduction of the topics of polycontextural formal systems, like polylogics, poly-arithmetic or polysemiotics, has to deal with the question of a privileged number of a possible extension of 2-valued logics, semiotics and arithmetic. This has been thematized at different places and can’t be exposed in extenso in this Short Study to Polysemiotics.3

1.2.1. Gunther’s approach to many-valued logics

In the advent of many-valued logics there was a big run to find a privileged number of truth-values, logical functions and their semantic interpretation. Gunther’s Program. Each single value and each single logical function is entitled to have a logical meaning. It is absurd to chase for the meaning of logical values and functions for arbitrary many-valued systems. Special value classes of some interest had been studied by logicians for 2, 3, 4, and infinite. Hence, a method, like the arithmetic position system which is able to determine arbitrary numbers on a finite base system, has to be invented. This was Gunther’s approach to many-valued place-value systems (Stellenwertlogik). Semiotics, today, is still in a pre-decompositional, i.e. conceptionally static state of research, not necessarily in the spirit of Peirce’s ‘speculations’.

1.2.2. Gunther’s criticism of Peirce/Bense’s trinitarism

Gunther has taken the opportunity to write down and publish, what was clear at least since the advent of his place-valued logics in the 50s. That the restriction of Peirce and his decade long friend Max Bense is a heritage of Western and Christian thinking, which was conceived by Gunther as dead, at least since Nietzsche and American Cybernetics.

1.2.3. Beyond Gunther’s stance on numbers

Gunther repeated the argumentation of Aristotle against a privileged number, say for his m-valued polycontextural logic, but was nevertheless the only one who himself introduced a (Neo)Pythagorean concept and some formalism of transclassic numbers, called “Philosophical numbers” (Gattungszahlen). In short: In polycontextural logic, no special number is privileged because each number has its own specific characteristics, hence its own privilege. With this paradoxical characterization of ‘privileged’/unprivileged numbers, the whole idea of a privileged number in the traditional sense is obsolete. But this polycontextural magnitude of de-privileged privileges is based on a strategy of a finite structure, the number 4 of ‘tetraktomai’, i.e. of doing the tetraktys, also called proemial relationship or diamond strategies. Again, this number of the praxis of tetraktomai, i.e. diamodization, isn’t a member of any arithmetical number system.4

1.2.4. Toth’s criticism of Bense’s triadic-trichotomic semiotics

"Um es kurz zu sagen: Bense hatte - es ist fast nicht zu glauben - n-äre und n-adische Logiken verwechselt: Obwohl die Peirce-Bense-Semiotik triadisch ist, bleibt sie dennoch binär, und das, obwohl sie einen zehnfach ausdifferenzierten Realitätsbegriff besitzt.” (Toth, Semiotische Strukturen und Prozesse, 2008). This, and other ebooks by Alfred Toth at:

2. Dissemination of semiotics

Interaction between different logical or semiotic systems is depending on the architectonics of the framework. In the proposed case, only two cases are presented.

First an architectonics based on a decomposition of the system into (2, 2)-subsystem. And second, an architectonics based on the decomposition of the system into (3, 2)-
and subsystems.

The decomposition into \((2, 2)\)-subsystems of 3-contextural systems corresponds to the usual polycontextual approach as introduced by Gotthard Gunther for his *place-valued* logic. It can be understood as a dissemination of *contextures* towards polycontexturality as the base for polycontextural logics in general.

This strategy of decomposing Peirce/Bense/Toth-semiotics into its dyadic-dichotomic parts opens up the possibility for a *polycontextural* approach to a logic, arithmetic and categorification of semiotics as a mediation of semiotically, logically and categorically independent elementary contextures of a mediated compound. This approach is in strict contrast to a modeling of triadic-trichotomic semiotics with methods of classical relation, set and category theory.

The \((3, 3)\)-subsystem decomposition of 4-contextural systems, albeit it goes back to my early studies of polycontexturality, has been introduced recently for a new formalization of semiotics towards polysemiotics.

Polysemiotics are disseminating, in a first step, classical triadic-trichotomic semiotics, \(\text{Sem}^{(3,2)}\), over different kenomic places to build more complex configurations.

### 2.1. Contextural decomposition triadic systems

#### 2.1.1. Unary matrix\(^{(3,1)}\)

\[
\text{Sem}^{(3,1)} = (\text{Sem}^1, \text{Sem}^2, \text{Sem}^3)
\]

Valuation \((\text{val})\) of \(\text{Sem}\):

\[
\text{val}(\text{Sem}^1, \text{Sem}^2, \text{Sem}^3) = (1_{1,3}, 2_{1,2}, 3_{2,3})
\]

Hence,

\[
\text{Sem}^1 = \text{Sem}_{1,3}
\]

\[
\text{Sem}^2 = \text{Sem}_{1,2}
\]

\[
\text{Sem}^3 = \text{Sem}_{2,3}
\]

Matching conditions:

\[
(1)_1 \not\equiv (1)_3
\]

\[
(2)_1 \not\equiv (2)_2
\]

\[
(3)_2 \not\equiv (3)_3
\]

#### 2.1.2. Binary matrix\(^{(3,2)}\) and scheme\(^{(3,2)}\)
\[ \text{Sem}^{(3,2)} = \text{Sem}^{(3,1)} \times \text{Sem}^{(3,1)} = (1_{1.1}, 2_{1.2}, 3_{2.3}) \times (1_{1.1}, 2_{1.2}, 3_{2.3}) \]
\[ \text{Sem}^{(3,2)} = [(\text{Sem}^1 \times \text{Sem}^1), (\text{Sem}^2 \times \text{Sem}^2), (\text{Sem}^3 \times \text{Sem}^3)] : \]
\[ \text{val}(\text{Sem}^1 \times \text{Sem}^1) = (1, 2)_{1} \times (1, 2)_{1} \]
\[ \text{val}(\text{Sem}^2 \times \text{Sem}^2) = (2, 3)_{2} \times (2, 3)_{2} \]
\[ \text{val}(\text{Sem}^3 \times \text{Sem}^3) = (1, 3)_{3} \times (1, 3)_{3} \]

Matching conditions:
\[ (1, 1)_{1} \not\equiv (1, 1)_{3} \]
\[ (2, 2)_{1} \not\equiv (2, 2)_{2} \]
\[ (3, 3)_{2} \not\equiv (3, 3)_{3} \]

**Scheme of Sem^{(3,2)}**:

\[
\text{Semiotics}^{(3,2)} = \begin{bmatrix}
(1,1)_{1.1} & (1,2)_{1} & (1,3)_{3} \\
\downarrow \times & \downarrow \times & \downarrow \\
(2,1)_{1} & (2,2)_{1.2} & (2,3)_{2} \\
\downarrow \times & \downarrow \times & \downarrow \\
(3,1)_{3} & (3,2)_{2} & (3,3)_{2.3}
\end{bmatrix}
\]

**Sub-system decomposition of Sem^{(3,2)}**:

\[
\text{sub-system}_1 = \begin{bmatrix}
(1,1) \rightarrow (1,2) \\
\downarrow \times \\
(2,1) \rightarrow (2,2)
\end{bmatrix}
\]
\[
\text{sub-system}_2 = \begin{bmatrix}
(2,2) \rightarrow (2,3) \\
\downarrow \times \\
(3,2) \rightarrow (3,3)
\end{bmatrix}
\]
\[
\text{sub-system}_3 = \begin{bmatrix}
(1,1) \rightarrow (1,3) \\
\downarrow \times \\
(3,1) \rightarrow (3,3)
\end{bmatrix}
\]
3 - contextual semiotic matrix

\[
\text{Sem}^{(3,2)} = \begin{pmatrix}
0 & 1.1_{1,3} & 2.1_{1,2} & 3.1_{1,3} \\
1.1_{1,3} & 1.2_1 & 2.1_1 & 3.1_1 \\
2.1_{1,2} & 2.2_1 & 2.3_2 & 3.2_2 \\
3.1_{1,3} & 3.2_2 & 3.3_2 & 3.3_3
\end{pmatrix}
\]

The mediation scheme of \( \text{Semiotics}^{(3,2)} \):

\[
\text{mediation}(\text{Semiotics}^{(3,2)}) = \begin{pmatrix}
(1.1)_1 & \rightarrow & (2.2)_1 & \square \\
\square & \square & \square & \square \\
\square & \square & \square & \square \\
(1.1)_3 & \rightarrow & (3.3)_3 & \square
\end{pmatrix}
\]

Chiastic structure

Order relations = \( \{(1.1)_1 \rightarrow (2.2)_1, \}

\{(2.2)_2 \rightarrow (3.3)_2, \}

\{(1.1)_3 \rightarrow (3.3)_3\}\}

Exchange relation = \( \{(2.2)_1 \leftrightarrow (2.2)_2, \}\}

Coincidence relations = \( \{ (1.1)_1 - (1.1)_3, \}

\{ (3.3)_2 - (3.3)_3, \}\}

For systems, \( m = 3, n = 2 \), the matrix\( ^{3,2} \) and scheme\( ^{3,2} \) representation coincide.

Sign classes for classical Semiotics
Classical semiotics is not mediating its sub-systems, hence, no matching conditions are required. Therefore, classical semiotics is forced to introduce externally different restriction rules to determine the set of accepted sign classes.

Sign classes are traditionally defined by:
\[ ZR = \{a \mapsto b, (a \mapsto b \mapsto c)\} \]

for
\[ a = \{1.1, 1.2, 1.3\} \]
\[ b = \{2.1, 2.2, 2.3\} \]
\[ c = \{3.1, 3.2, 3.3\} \]

General sign relation:
\[ ZR = <3.x, 2.y, 1.z> \text{ mit } x, y, z \in \{1, 2, 3\} \]
with \[ x \leq y \leq z. \]

Resulting in the 10 sign classes:
\[ 3.1.2.1.1.1 \quad 3.1.2.3.1.3 \]
\[ 3.1.2.1.1.2 \quad 3.2.2.2.1.2 \]
\[ 3.1.2.1.1.3 \quad 3.2.2.2.1.3 \]
\[ 3.1.2.2.1.2 \quad 3.2.2.3.1.3 \]
\[ 3.1.2.2.1.3 \quad 3.3.2.3.1.3 \]

Classical semiotics is not mediating its sub-systems, hence, no matching conditions are required. Therefore, classical semiotics is forced to introduce externally different restriction rules to determine the set of accepted sign classes.

**Sign classes for Sem\(^{3,1,2}\)**
Super-operators for semiotic mappings

Independent of a specification of sign classes by accepting or abolishing the restriction rules for semiotics (Toth, Ghost, p.9), mappings from sign class to sign class might be classified by the super-operators as they are defined in polycontextural logic:

\[
\text{decomp}[3.2, 2.1.1.1] = \begin{bmatrix}
3.2, 2.1, \\
\ldots, 2.2, 1.1 \\
3.2, \ldots, 1.1 \\
\end{bmatrix}
\]

\[
\text{decomp}[3.2.2.2.1.2] = \begin{bmatrix}
3.2, 2.1, \\
\ldots, 2.2, 1.2 \\
3.2, \ldots, 1.2 \\
\end{bmatrix}
\]

\[
\text{decomp}[2.2.2.1.2] = \begin{bmatrix}
2.2, 2.1, \\
\ldots, 2.1, 1.2 \\
2.2, \ldots, 1.2 \\
\end{bmatrix}
\]

**Translation**

a. \[3.1.2.1.1.1 \rightarrow (3.1.3.2.1.1.1.1.3)\]
\[\rightarrow [(3.1.3 \text{ xx } 1.1.3), (\text{ xx } 2.1.1.1.1.1)]\]

b. \[3.2.2.1.1.1 \rightarrow (3.2.2 \text{ xx } 1.1.1.3)\]
\[\rightarrow [(3.2.1 \text{ xx } \text{ xx}), (\text{ xx } 2.1.1.1.1.1), (\text{ xx } \text{ xx } 1.1.3)]\]

c. \[3.1.2.1.1.1 \rightarrow (3.1.3.2.1.1.1.1.3)\]
\[\rightarrow [(3.1.3 \text{ xx } 1.1.3), (\text{ xx } 2.1.1.1.1.1)]\]

Super-operators for semiotic mappings

Independent of a specification of sign classes by accepting or abolishing the restriction rules for semiotics (Toth, Ghost, p.9), mappings from sign class to sign class might be classified by the super-operators as they are defined in polycontextural logic:
Considering the 3 principles of semiotic restrictions, i.e. triadic diversity, degenerative triadic order and trichotomic inclusion, permutation and reduction operations might add some more structure to semiotics without surpassing its general framework. The operation of permutation, which had a case as a dualisation (Bense) only, is complemented by Toth's concept of transpositions.
2.1.3. Ternary matrix\(^{(3, 3)}\) and scheme\(^{(3, 3)}\)

\[
\text{Sem}^{(3, 3)} = \left( \text{Sem}^{(3, 1)} \times \text{Sem}^{(1, 1)} \times \text{Sem}^{(3, 1)} \right) = \\
\begin{bmatrix}
\text{Sem}^1 \times \text{Sem}^1 \times \text{Sem}^1 \\
\text{Sem}^2 \times \text{Sem}^2 \times \text{Sem}^2 \\
\text{Sem}^3 \times \text{Sem}^3 \times \text{Sem}^3
\end{bmatrix}
\]

\[
\text{val} \left( \text{Sem}^{(3, 3)} \right) = \\
\begin{bmatrix}
(1, 1, 3) \\
(1, 3, 2) \\
(1, 3, 2)
\end{bmatrix}
\]

\[
\text{val} \left( \text{Sem}^1 \times \text{Sem}^1 \times \text{Sem}^1 \right) = (1, 2) \times (1, 2) \times (1, 2)
\]
\[
\text{val} \left( \text{Sem}^2 \times \text{Sem}^2 \times \text{Sem}^2 \right) = (2, 3) \times (2, 3) \times (2, 3)
\]
\[
\text{val} \left( \text{Sem}^3 \times \text{Sem}^3 \times \text{Sem}^3 \right) = (1, 3) \times (1, 3) \times (1, 3)
\]

Matching conditions:
\[
(1, 1, 1)_1 \equiv (1, 1, 1)_3
\]
\[
(2, 2, 2)_1 \equiv (2, 2, 2)_2
\]
\[
(3, 3, 3)_2 \equiv (3, 3, 3)_3
\]

Sign classes \(\text{Sem}^{(3, 3)}\)
\[
(3.1.2.1.3) \in \text{Sem}^{(3, 2)}
\]
\[
(3.1.3.2.1.3) \in \text{Sem}^{(3, 3)}
\]

\[
\text{3 - contextual semiotic matrix}^{(3, 3)}
\]

\[
\begin{bmatrix}
\text{MM} & .1_{1,3} & .2_{1,2} & .3_{2,3} \\
1_{1,3} & 1.1_{1,3} & 1.2 & 1.3 \\
2_{1,2} & 2.1 & 2.2_{1,2} & 2.3 \\
3_{2,3} & 3.1 & 3.2 & 3.3_{2,3}
\end{bmatrix}
\]

\[
\sum = 27
\]

Different presentation of the matrix\(^{(3, 3)}\)
(Toth, Strukturen + Prozesse, p.36, 2008)
Semiotics scheme for $\text{Sem}^{(3,3)}$

$\text{Sem}^{(3,3)}$ – scheme

\[
\begin{align*}
(1.1.1)_{1,3} & \rightarrow (1.2) \rightarrow (1.2.1) \rightarrow (1.2.2) \rightarrow (1.1.3) \rightarrow (1.3.1) \rightarrow (1.3.3) \\
\downarrow & \quad \downarrow & \quad \downarrow & \quad \downarrow & \quad \downarrow & \quad \downarrow & \quad \downarrow & \quad \downarrow & \quad \downarrow \\
(2.1.1) & \rightarrow (2.1.2) \rightarrow (2.2.1) \rightarrow (2.2.2)_{1,2} \rightarrow (2.2.3) \rightarrow (2.3.2) \rightarrow (2.3.3) \\
\downarrow & \quad \downarrow & \quad \downarrow & \quad \downarrow & \quad \downarrow & \quad \downarrow & \quad \downarrow & \quad \downarrow & \quad \downarrow \\
(3.1.1) & \rightarrow (3.1.3) \rightarrow (3.3.1) \rightarrow (3.2.2) \rightarrow (3.2.3) \rightarrow (3.3.2) \rightarrow (3.3.3)_{23} \\
\sum & = 21
\end{align*}
\]
Possible constellation of the matrix of Sem\(^{(3,3)}\), like (1, 2, 3), (1, 3, 2), that is, constellations with \(i\neq j\neq k\), for the ternary function AxBxC of the matrix are not decomposable into Sem\(^{(2,2)}\) - subsystems of the semiotic scheme.

For systems \(m, n\geq 3\), well known combinatorial problems of decomposition into...
As a consequence of the matching conditions of decomposition, the semiotic system \( \text{Sem}^{(3, 3)} \) is not delivering \( 3^9 = 19683 \) different decomposable semiotic functions as demanded by (Toth, Gost, p. 9, 2008).

\[
\sum \text{ scheme} = 40, \text{ matrix} = 4 \times 4 \times 4 = 64
\]

### 2.2. Semiotic decomposition of tetradic systems

#### 2.2.1. Unary tetradic matrix

\[
\text{Sem}^{(1, 3)} = (\text{Sem}^1, \text{Sem}^2, \text{Sem}^3, \text{Sem}^4)
\]

\[
\text{val} \left( \text{Sem}^{(1, 3)} \right) = \begin{cases} 1_1 \rightarrow 2_1 \rightarrow 3_1 \rightarrow \_ \\ \_ \rightarrow 2_2 \rightarrow 3_2 \rightarrow 4_2 \\ 1_3 \rightarrow 2_3 \rightarrow \_ \rightarrow 4_3 \\ 1_4 \rightarrow \_ \rightarrow 3_4 \rightarrow 4_4 \end{cases}
\]

\[
\text{val} \left( \text{Sem}^{(1, 3)} \right) = (1_1, 2_1, 3_1, 4_1, 2_2, 3_2, 4_2, 1_3, 2_3, 3_3, 4_3, 1_4, 3_4, 4_4).
\]

#### 2.2.2. Binary tetradic matrix
\[
\text{Sem}^{[4,2,3]} = \text{Sem}^{[4,1,3]} \times \text{Sem}^{[4,1,3]} = \\
[\{(\text{Sem}^1 \times \text{Sem}^1), (\text{Sem}^2 \times \text{Sem}^2), (\text{Sem}^3 \times \text{Sem}^3), (\text{Sem}^4 \times \text{Sem}^4)\}]
\]

\[
\text{val}(\text{Sem}^{[4,1,3]} \times \text{Sem}^{[4,1,3]}) = \\
(1_{1.3.4}, 2_{1.3.4}, 3_{1.3.4}, 4_{1.3.4}) \times (1_{1.3.4}, 2_{1.3.4}, 3_{1.3.4}, 4_{1.3.4})
\]

with:

\[
\text{val}(\text{Sem}^1 \times \text{Sem}^1) = (1, 2, 3) \times (1, 2, 3)
\]

\[
\text{val}(\text{Sem}^2 \times \text{Sem}^2) = (2, 3, 4) \times (2, 3, 4)
\]

\[
\text{val}(\text{Sem}^3 \times \text{Sem}^3) = (1, 2, 4) \times (1, 2, 4)
\]

\[
\text{val}(\text{Sem}^4 \times \text{Sem}^4) = (1, 3, 4) \times (1, 3, 4)
\]

As presented at "Semiotics in Diamonds" a coloring of the subsystems might emphasize [link](http://www.thinkartlab.com/pld/lola/Semiotics-in-Diamonds/Semiotics-in-Diamonds.html)
\[
\text{val}\left( \text{Sem}^{(6,1,3)} \times \text{Sem}^{(4,1,3)} \right) = \\
\begin{array}{cccc}
\text{MM} & 1 & 2 & 3 & 4 \\
1 & 1.1_{1,3,4} & 1.2_1 & 1.3_1 & 1.4_1 \\
2 & 2.1_1 & 2.2_{1,2,3} & 2.3_1 & 2.4_1 \\
3 & 3.1_1 & 3.2_1 & 3.3_{1,2,4} & 3.4_1 \\
4 & 4.1_1 & 4.2_1 & 4.3_1 & 4.4_1 \\
\end{array}
\]

\[
\text{sem}^1 \times \text{sem}^1 = \\
\begin{array}{cccc}
\text{MM} & 1 & 2 & 3 & 4 \\
1 & 1.1_1 & 1.2_1 & 1.3_1 & 1.4_1 \\
2 & 2.1_1 & 2.2_{1,2} & 2.3_{1,2} & 2.4_{1,2} \\
3 & 3.1_1 & 3.2_{1,2} & 3.3_{1,2,4} & 3.4_{1,2} \\
4 & 4.1_1 & 4.2_{1,2} & 4.3_{1,2} & 4.4_{1,2} \\
\end{array}
\]

\[
\text{sem}^2 \times \text{sem}^2 = \\
\begin{array}{cccc}
\text{MM} & 1 & 2 & 3 & 4 \\
1 & 1.1_{1,3} & 1.2_{1,3} & 1.3_1 & 1.4_1 \\
2 & 2.1_{1,3} & 2.2_{1,2,3} & 2.3_{1,2} & 2.4_{1,2,3} \\
3 & 3.1_{1,3} & 3.2_{1,2} & 3.3_{1,2,4} & 3.4_{1,2} \\
4 & 4.1_{1,3} & 4.2_{1,2} & 4.3_{1,2} & 4.4_{1,2} \\
\end{array}
\]

\[
\text{sem}^3 \times \text{sem}^3 = \\
\begin{array}{cccc}
\text{MM} & 1 & 2 & 3 & 4 \\
1 & 1.1_{1,3,4} & 1.2_{1,3} & 1.3_{1,4} & 1.4_{1,3,4} \\
2 & 2.1_{1,3} & 2.2_{1,2,3} & 2.3_{1,2} & 2.4_{1,2,3} \\
3 & 3.1_{1,3} & 3.2_{1,2} & 3.3_{1,2,4} & 3.4_{1,2,4} \\
4 & 4.1_{1,3} & 4.2_{1,2} & 4.3_{1,2} & 4.4_{1,2} \\
\end{array}
\]

\[
\text{sem}^4 \times \text{sem}^4 = \\
\begin{array}{cccc}
\text{MM} & 1 & 2 & 3 & 4 \\
1 & 1.1_{1,3,4} & 1.2_{1,3} & 1.3_{1,4} & 1.4_{1,3,4} \\
2 & 2.1_{1,3} & 2.2_{1,2,3} & 2.3_{1,2} & 2.4_{1,2,3} \\
3 & 3.1_{1,3} & 3.2_{1,2} & 3.3_{1,2,4} & 3.4_{1,2,4} \\
4 & 4.1_{1,3} & 4.2_{1,2} & 4.3_{1,2} & 4.4_{1,2} \\
\end{array}
\]

4 – contextual semiotic matrix

\[
\text{Sem}^{(4,1,2)} = \\
\begin{array}{cccc}
\text{MM} & 1 & 2 & 3 & 4 \\
1 & 1.1_{1,3,4} & 1.2_{1,3} & 1.3_{1,4} & 1.4_{1,3,4} \\
2 & 2.1_{1,3} & 2.2_{1,2,3} & 2.3_{1,2} & 2.4_{1,2,3} \\
3 & 3.1_{1,3} & 3.2_{1,2} & 3.3_{1,2,4} & 3.4_{1,2,4} \\
4 & 4.1_{1,3} & 4.2_{1,2} & 4.3_{1,2} & 4.4_{1,2} \\
\end{array}
\]

Sign classes for \text{Sem}^{(4,1,2)}
\[ Z_{R}^{(3, 2)} = < 3. x, 2. y, 1. z > \text{ with } x, y, z \in \{1, 2, 3\} \]

\[ Z_{R}^{(4, 2)} = [Z_{R}^{1}, Z_{R}^{2}, Z_{R}^{3}, Z_{R}^{4}] :\]

\[ Z_{R}^{1} = < 3. x, 2. y, 1. z, \_ \_ \_ > \]
\[ Z_{R}^{2} = < \_ \_ \_, 3. x, 2. y, 1. z > \]
\[ Z_{R}^{3} = < 3. x, 2. y, \_ \_ \_, 1. z > \]
\[ Z_{R}^{4} = < 3. x, \_ \_ \_, 2. y, 1. z > \]

\[
\text{decomp}
\begin{bmatrix}
3. x, 2. y, 1. z, \_ \_ \\
\_ \_ \_, 3. x, 2. y, 1. z \\
3. x, 2. y, \_ \_ \_, 1. z \\
3. x, \_ \_ \_, 2. y, 1. z
\end{bmatrix}
= [4. a, 3. b, 2. c, 1. d]
\]

\[
\text{comp}
\begin{bmatrix}
3. x, 2. y, 1. z, \_ \_ \\
\_ \_ \_, 3. x, 2. y, 1. z \\
3. x, 2. y, \_ \_ \_, 1. z \\
3. x, \_ \_ \_, 2. y, 1. z
\end{bmatrix}
= [4. a, 3. b, 2. c, 1. d]
\]

**Matching conditions**

\((3. x)_1 \equiv (3. x)_3 \equiv (3. x)_4\)

\((2. y)_1 \equiv (3. x)_2 \equiv (2. y)_3\)

\((1. z)_1 \equiv (2. y)_2 \equiv (2. y)_4\)

\((1. z)_2 \equiv (1. z)_3 \equiv (1. z)_4.\)

Each sign class of \(\text{Sem}^{(4, 2)}\) is decomposable into its \(\text{Sem}^{(3, 2)}\) sign classes.

**Example**

\([4.3\ 3.2\ 2.1\ 1.1] \in \text{Sem}^{(4, 2)}\)

\[
\text{decomp}([4.3\ 3.2\ 2.1\ 1.1]) = \begin{bmatrix}
(4.3, 3.2, 2.1, \_ \_ \_) \in \text{Sem}^1 \\
(\_ \_ \_, 3.2, 2.1, 1.1) \in \text{Sem}^2 \\
(4.3, 3.2, \_ \_ \_, 1.1) \in \text{Sem}^3 \\
(4.3, \_ \_ \_, 2.1, 1.1) \in \text{Sem}^4
\end{bmatrix}
\]

\([4.3\ 3.2\ 2.1\ 1.1] \in \text{Sem}^{(4, 2)}\)

**2.2.3. (Some) Sign classes for \text{Sem}^{(4, 2)}**
2.3. Interplay of semiotics, logics and arithmetic

A study of polycontextural semiotics, focused on semiotics alone, is not yet guaranteeing its polycontexturality. The logical and arithmetical status of semiotics, mono- and polycontextural, remains undetermined if its corresponding logics are not determined.

There are many ways open to formalize, logically and arithmetically, semiotics and polysemiotics. Good candidates are the logics from the modal logic pool. Nevertheless, they have all to be classified as mono-contextural.

For the purpose of this introductory sketch of a descriptive characterization of the idea of poly-semiotics, it might be sufficient to hint to the decision to use 3-contextural subsystems of 4-contextural logics and arithmetics. Instead of the usual decomposition into elementary contextures.

As a consequence, it turns out that the apparatus of classical category theory is not adequate to formalize semiotics and polysemiotics.
Hence, from a 4-contextural logic, $\text{Log}^{(4)}$, with its six 2-contextures, $\text{Log}^{(4,2)}$, its four 3-contextures, $\text{Log}^{(4,3)}$, only the four 3-contextural subsystems are in direct correspondence to the 4-contextural (poly)semiotics, decomposed into its 3-contextural semiotic parts.

\[
\text{Graphematics}^{(4,3,2)} = (\text{Sem}^{(4,3,2)}, \text{Log}^{(4,3)}, \text{Arith}^{(4,3)})
\]

with

\[
\text{Sem}^{(4,2)} = (\text{Sem}^{(3,1)}, \text{Sem}^{(3,2)}, \text{Sem}^{(3,3)}, \text{Sem}^{(3,4)})
\]

\[
\text{Log}^{(4,2)} = (\text{Log}^{(3,1)}, \text{Log}^{(3,2)}, \text{Log}^{(3,3)}, \text{Log}^{(3,4)})
\]

\[
\text{Arith}^{(4,2)} = (\text{Arith}^{(3,1)}, \text{Arith}^{(3,2)}, \text{Arith}^{(3,3)}, \text{Arith}^{(3,4)})
\]

$\text{Sem}^{(4,2)}$ is a 4-contextural semiotics, which is realizing the paradigmatic and conceptual transformations of the 4-contextural logics $\text{Log}^{(4)}$ and arithmetic $\text{Arith}^{(4)}$.

$\text{Log}^{(4,2)}$ is a 4-contextural logic, which is realizing the structural and deductional transformations of the 4-contextural semiotics $\text{Sem}^{(4)}$ and arithmetic $\text{Arith}^{(4,2)}$.

$\text{Arith}^{(4,2)}$ is a 4-contextural arithmetic, which is realizing the structural and computational transformations of the 4-contextural semiotics $\text{Sem}^{(4)}$ and logics $\text{Log}^{(4,2)}$.

$\text{Graphematics}^{(4,3,2)}$ is the interplay of semiotics, logics and arithmetic of complexity $\text{compl}^{(4,2)}$.

### 2.4. Multi-dimensional and polycontextural semiotics

#### 2.4.1. Toth’s multi-dimensional semiotics

**Scheme of a 3-dimensional semiotics**

Toth introduced in (Transit-Korridor, 2009) a 3-dimensional sign relation $3-ZKL = ([a.3,b][c,2,d][e,1,f])$ with its 27 variations.

**Examples**

\[
\begin{align*}
(1.3.3 & 1.2.2 1.1.1) & (1.3.1 & 1.2.2 1.1.3) \\
(2.3.3 & 2.2.2 2.1.1) & (2.3.1 & 2.2.2 2.1.3) \\
(3.3.3 & 3.2.2 3.1.1) & (3.3.1 & 3.2.2 3.1.3).
\end{align*}
\]
2.4.2. Polycontextural (uni-dimensional) semiotics

**Scheme of a Transit – Korridor:**

\[ TK = \{ <a, 3.3b, c.2.2d, e.1.1f > \} \]

with \( a, c, e \in \{1, 2, 3\} \) and \( b, d, f \in \{1, 2, 3, 4\} \).

In general (I guess):

\[ m = ZKL = \left( \left( a.3.3...3b_1b_2...b_m \right) \left( c.2.2...2d_1d_2...d_m \right) \left( e.1.1...1f_1f_2...f_m \right) \right) \]

with \( a, c, e \in \{1, 2, 3\} \) and \( b, d, f \in \{1, 2, ..., m\} \).

\[ ZR = \left( a \rightarrow b, \left( a \rightarrow b \rightarrow c \right), \left( a \rightarrow b \rightarrow c \rightarrow d \right) \right) \]

for

\[ a = \{ 1.1, 1.2, 1.3, 1.4 \} \]
\[ b = \{ 2.1, 2.2, 2.3, 2.4 \} \]
\[ c = \{ 3.1, 3.2, 3.3, 3.4 \} \]
\[ d = \{ 4.1, 4.2, 4.3, 4.4 \} \]

General sign relation for \( ZR^{(4)} \):

\[ ZR^{(4)} = < 4, u, x, y, 1, z > \]

with \( u, x, y, z \in \{1, 2, 3, 4\} \)

and \( u \preceq x \preceq y \preceq z \)

In general:

\[ \text{Sem}^{(4, 2)} = [m.a_m, m-1.a_{m-1}, ..., 2.a_2, 1.a_1] \]

2.4.3. Comparisons

\[ 2-ZKL = < 3, x, 2, y, 1, z > \]

with \( x, y, z \in \{1, 2, 3\} \) and \( x \preceq y \preceq z \implies 10 \) sign classes

\[ 3-ZKL = \left( \left( a.3.3b \right) \left( c.2.d \right) \left( e.1.f \right) \right) \implies 27 \text{ sign classes} \]

\[ \text{Sem}^{(4, 2)} - \text{scheme} = [4, a, 3, b, 2, c, 1, d] \implies 35 (??) \]

3. Interactivity in poly-semiotics
3.1. Interactions between (2,2)-subsystems of Sem\(^{(3,2)}\)

Interactional semiotic functions

Interactions, in the form of transjunctions, are of great importance in polycontextural logic. In fact, from a combinatorial point of view, most polynlogical functions are transjunctional. Therefore, they should deserve a prominent place in a polycontextural semiotics. At this place, not more than a short hint can be given.

\[
\begin{align*}
\text{(transjunction, junction, junction)}_{\text{Polylogic}} & \Rightarrow \text{(interaction, action, action)}_{\text{Polysemiotics}} \\
\text{Sem}_{\text{inter, act, act}}^{(3,2)} & = \left(\text{Sem}_{\text{inter, act, act}}^{(3,1)} \times \text{Sem}_{\text{inter, act, act}}^{(3,1)}\right)_{\text{inter, act, act}} = \\
& = \left[\left(\text{Sem}\times\text{Sem}\right)_{2,3} \times \left(\text{Sem}\times\text{Sem}\right)_{2,3} \times \left(\text{Sem}\times\text{Sem}\right)_{2,3}\right]: \\
\text{val}_{\text{inter}}\left(\text{Sem}\times\text{Sem}\right)_{1} & = (1, 1)_{1} \times (2, 2)_{1} \parallel (2, 3)_{2,3} \times (3, 2)_{2,3}, \\
\text{val}_{\text{act}}\left(\text{Sem}\times\text{Sem}\right)_{2} & = (2, 3)_{2} \times (2, 3)_{2}, \\
\text{val}_{\text{act}}\left(\text{Sem}\times\text{Sem}\right)_{3} & = (1, 3)_{3} \times (1, 3)_{3}, \\
\text{with } (2, 3)_{2,3} \times (3, 2)_{2,3} & = (2, 3)_{2,3} \times (3, 2)_{2,3} \\
\end{align*}
\]

Operational notation

\[
\text{Op}_{\text{inter, act, act}}: \left[\left(\text{Sem}\times\text{Sem}\right)_{1}, \left(\text{Sem}\times\text{Sem}\right)_{2}, \left(\text{Sem}\times\text{Sem}\right)_{3}\right] \\
= \left[\left(\text{Sem}\times\text{Sem}\right)_{1}, \left(\text{Sem}\times\text{Sem}\right)_{2}, \left(\text{Sem}\times\text{Sem}\right)_{3}\right]
\]

or short:

\[
\text{Op}_{\text{inter, act, act}} : \text{Sem}_{\text{inter, act, act}}^{(3,2)} \Rightarrow \text{bif}_{1,2,3}(\text{d}_{2,3}(\text{Sem}_{\text{inter, act, act}}^{(3,2)}))
\]

\[
\text{inter, act, act} = [\ast, \circ, \circ]
\]

\[
\text{Sem}_{\text{inter, act, act}}^{(3,2,2)} = \\
\begin{pmatrix}
[\ast, \circ, \circ] & 1 & 2 & 3 \\
1 & 1.1 & 1.3 & 2.3 & 2.3 & 1.3 & 3 \\
2 & 3.2 & 3.2 & 2.2 & 1.2 & 2.3 & 2 \\
3 & 3.1 & 3.2 & 3.3 & 3.2 & 2 & 3.3 \times 2.3
\end{pmatrix}
\]
Different modi of interaction with $\text{Sem}^2$:

\[
\begin{array}{ccc}
1 & 2 & 3 \\
\text{id}_1 & \alpha_2 \cdot 3 & \alpha_3 \\
\alpha_2 & \alpha_2 \cdot 3 & \text{id}_2 \\
\alpha_3 & \alpha_3 & \alpha_2 \cdot 3
\end{array}
\begin{array}{ccc}
1 & 2 & 3 \\
\text{id}_1 & \alpha_2 \cdot 3 & \alpha_3 \\
\alpha_2 & \alpha_2 \cdot 3 & \text{id}_2 \\
\alpha_3 & \alpha_3 & \alpha_2 \cdot 3
\end{array}
\]

General distribution tables for [inter, act, act]

\[
\begin{array}{ccc}
1 & 2 & 3 \\
\text{id}_2 & \alpha_2 \cdot 3 & \alpha_3 \\
\alpha_2 & \alpha_2 \cdot 3 & \text{id}_2 \\
\alpha_3 & \alpha_3 & \alpha_2 \cdot 3
\end{array}
\begin{array}{ccc}
1 & 2 & 3 \\
\text{id}_2 & \alpha_2 \cdot 3 & \alpha_3 \\
\alpha_2 & \alpha_2 \cdot 3 & \text{id}_2 \\
\alpha_3 & \alpha_3 & \alpha_2 \cdot 3
\end{array}
\]

3.2. Interactions between (3, 3)-subsystems of $\text{Sem}^{(4,2,3)}$
3.3. Interaction and reflectionality

Following the concepts and methods developed in "ConTeXtures. Programming Dynamic Complexity" (Kaehr, 2005), short hints of their application to disseminated semiotics are given. Both, the bracket and the table notation are emphasizing the architectonic structure of reflection and interaction.
Reflexions in $\text{Sem}^{(1,2)}$

\[
\begin{bmatrix}
O_1 \\
O_2 \\
O_3
\end{bmatrix}
= 
\begin{bmatrix}
M_1 M_2 M_3 \\
M_1 M_2 M_3 \\
M_1 M_2 M_3
\end{bmatrix}
= 
\begin{bmatrix}
\text{Sem}_{110} \\
\text{Sem}_{222} \\
\text{Sem}_{033}
\end{bmatrix}
\]

Iterative reflection in $\text{Sem}^{(1,2)}$

\[
\begin{bmatrix}
O_1 \\
O_2 \\
O_3
\end{bmatrix}
= 
\begin{bmatrix}
M_1 M_2 M_3 \\
M_1 M_2 M_3 \\
M_1 M_2 M_3
\end{bmatrix}
= 
\begin{bmatrix}
\text{Sem}_{110} \\
\text{Sem}_{222} \\
\text{Sem}_{033}
\end{bmatrix}
\]

\[
\text{reflection} 
\begin{bmatrix}
O_1 & O_2 & O_3 \\
M_1 & \text{sem}_1 & \text{sem}_2 & x \\
M_2 & \text{sem}_1 & \text{sem}_2 & \text{sem}_3 \\
M_3 & x & \text{sem}_2 & \text{sem}_3
\end{bmatrix}
\]

\[
\text{reflections} 
\begin{bmatrix}
O_1 & O_2 & O_3 \\
M_1 & \text{sem}_{1.1.1.1} & \text{sem}_2 & x \\
M_2 & \text{sem}_{1.1.1.1} & \text{sem}_2 & \text{sem}_3 \\
M_3 & x & \text{sem}_2 & \text{sem}_3
\end{bmatrix}
\]
4. Logification of semiotics

On the base of the introduced concepts for semiotic interactions interesting operations, rules and transformations (deductions) might be studied. Much of the work in semiotics and pre-semiotics is mainly descriptive, introducing its concepts and demonstrating some transformations. But there is nearly no work done for a kind of a deductive treatment in the semiotic field. This goes back mainly to the fact that semiotics in general has not yet accepted the concept of a polycontextural deductional system. On the other hand, a logical and deductive treatment of a genuine triadic-trichotomic semiotics by a classical logical approach goes hand in hand with a reduction procedure of the triadic-trichotomic complexity of classical semiotics to a dyadic-dichotomic model.

Logification of semiotics becomes relevant if we want to study semiotic operations in poly-semiotic systems. Like for logical systems, we can ask for
a specific state of the system in transformation. Transformations might produce conflicting results, similar to contradictions in logic. Such irregularities can be easily detected by the tableaux method for decomposed semiotic constellations. Therefore, deductive aspects, semiotic model theory (‘semantics’), proof theory, etc. of semiotic systems are accessible to be studied for their specific characteristics.

\[
\text{Sem}_{\{\text{inter}, \text{act}, \text{act}\}}^{(3,2,2)} = \begin{pmatrix}
\text{\{\ast, \circ, \circ\}} & 1 & 2 & 3 \\
1 & 1.1,1,3 & 2.3,2,3 & 1.3,3 \\
2 & 3.2,2,3 & 2.2,1,2 & 2.3,2 \\
3 & 3.1,3 & 3.2,3 & 3.3,2,3 \\
\end{pmatrix}
\]

\[
\text{logification} \rightarrow \begin{pmatrix}
\text{\{\ast, \vee, \wedge\}} & T_1,3 & F_1,2 & F_2,3 \\
T_1,3 & T_1,3 & F_2,3 & F_3 \\
F_1,2 & F_2,3 & F_1,2 & F_2 \\
F_2,3 & F_3 & F_2 & F_2,3 \\
\end{pmatrix}
\]

\[
\text{log}(\text{Sem}_{\{\ast, \circ, \circ\}}^{(3,2,2)})
\]

with:
\[
T_1,3 = 1.1,1,3 = t_1, t_3 \\
F_1,2 = 2.2,1,2 = f_1, f_2 \\
F_2,3 = 3.3,2,3 = f_2, f_3
\]

**Example**

\[
F_2(\text{Sem}_{\{\text{inter}, \text{act}, \text{act}\}}^{(3,2,2)}) = F_2(\text{Sem}_{\{\ast, \circ, \circ\}}^{(3,2,2)})
\]

\[
F_2 \bigg( \text{Sem}_{\{\ast, \circ, \circ\}}^{(3,2,2)} \bigg) = F_2 \bigg( \text{Sem}_{\{\ast, \circ, \circ\}}^{(3,2,2)} \bigg)
\]

\[
\begin{align*}
F_2 X & | F_2 Y \\
F_2 X & | F_2 Y \\
\end{align*}
\]

\[
\begin{align*}
t_2 \bigg( \text{Sem}_{\{\ast, \circ, \circ\}}^{(3,2,2)} \bigg) & \quad t_2 \bigg( \text{Sem}_{\{\ast, \circ, \circ\}}^{(3,2,2)} \bigg) \\
t_2 X & | t_2 Y \\
t_2 X & | t_2 Y \\
\end{align*}
\]
With such a mapping of semiotics onto logics, the whole machinery of combinatorics as studied earlier, might be directly applied (Kaehr, Mahler, 1993).

5. Interactions in diamonds

5.1. Interactions in diamonds

The new distinctions for diamonds between semiotic systems and their environments are allowing new kinds of interactions. Additionally, anchored semiotics and diamonds might be involved into even more radical interactions, like interventions and metamorphosis.

In general, it seems not to be realistic to deal with multi-leveled autonomous systems, say polysemiotics, in their isolation, without considering their complex interactions, e.g. interpenetrations (Luhmann), between heterarchically distributed sub-systems.

Interpenetration

"First, interpenetration is not a general relation between system and environment but an intersystem relation between systems that are environments for each other. In the domain of intersystem relations, the concept of interpenetration indicates a very specific situation, which must be distinguished above all from input/output relations (performances). We speak of “penetration” if a system makes its own complexity (and with it indeterminancy, contingency, and the pressure to select) available for constructing another system." (Niklas Luhmann)
A polylogical modeling of a semiotic diamond, $\text{Diamond}^{(d, 2)}_{\text{inter, act, act, act}}$, as $\text{Diamond}^{(d, 2)}_{(\psi \Theta, \gamma \Theta)}$ with interaction, transjunction, in sub-system$_2$ and its interference in the environmental sub-system$_4$, conjunction, gives some insight into the internal structure of a diamond with a weak interaction with sub-system$_4$. 

\[ \text{Diamond}^{(3, 2)}_{\text{inter, act, act, act}} = \begin{bmatrix} \begin{array}{c} \bullet \bullet \bullet \\ \bullet \bullet \bullet \\ \bullet \bullet \bullet \end{array} & (2.2)_1 \rightarrow (2.2)_2 \rightarrow (3.3)_3 \end{bmatrix} = \begin{bmatrix} \begin{array}{c} \text{S}_4 \text{S}_1 \\ \text{S}_3 \text{S}_2 \end{array} \end{bmatrix} \]

Correspondences for the diamond semiotics Sem$_4$ : $\delta[(2.2)_2] = (2.2)_4$, $\delta[(2.2)_1] = (2.2)_4$. 

\[ \text{Mediation scheme for semiotic diamond}^{(3, 2)} \]

\[ \text{Semiotic diamond scheme for interaction} \]

\[ \text{Diamond}^{(3, 2)}_{\text{inter, act, act, act}} = \begin{bmatrix} \begin{array}{c} \bullet \bullet \bullet \\ \bullet \bullet \bullet \\ \bullet \bullet \bullet \end{array} & 1 \begin{array}{c} 2 \\ 3 \end{array} \end{bmatrix} \begin{bmatrix} 1 \begin{array}{c} 1.1_{1,3} \\ 3.2_{2,3} \\ 3.1_{3,3} \end{array} & 2 \begin{array}{c} 2.3_{2,3} \\ 2.2_{1,2} \\ 3.2_{3,2} \end{array} & 3 \begin{array}{c} 1.3_{2,3} \\ 2.3_{1,2} \\ 3.3_{2,2} \end{array} \end{bmatrix} \begin{bmatrix} (2.2)_{(4,1)} \end{bmatrix} \]
5.2. Interactions between diamonds

As introduced in *Diamond Text Theory*, special interactions between diamonds are building networks of textemes. In this case, interaction between semiotic systems happens mediated by their neighboring environments.

Notes

1 *Computational* semiotics is interested in modeling interactions in computational scenarios. As much as there is no proper logic of interaction there is even much less development in computational semiotics. There is not even an awareness about the conceptual lack of interactivity constructs in theoretical semiotics. Despite the many *applicative* approaches to semiotic interactions, e.g. in human-computer interface research, it seems, that theoretical and foundational research for a semiotic theory of interaction and reflection is not supported.

Christopher R. Longyear, Further Towards a Triadic Calculus (Part 1, 2, 3)
http://www.vordenker.de/ggphilosophy/longyear-part_1.pdf

2 Independent of later steps of *abolishing* restrictions in the traditional definition of sign classes by Toth’s studies, the concept of a Cartesian product remains a fundamental construction to build up a semiotic system.

This fact allows to study the semiotic matrix under a different angle: the *polycontextural* approach of dissemination, i.e. distribution and mediation, of sub-systems as a mechanism to construct and to deconstruct the semiotic matrix. In this sense, an extension of the semiotic matrix for complex sign systems, called polysemiotics, is introduced.

To use Cartesian products doesn’t mean that they will remain stable in the development of a general theory of polylogics and polysemiotics. As shown at other places, what was a good starting point, became the main obstacle for further developments. Here again, the abstract mathematical frame (set and category theory) is not always adequate for the project of formalizing transclassical approaches.
This disseminative approach to the semiotics matrix allows to introduce a comparison of semiotic and logical constructions. As main operators of logical interaction, the polylogical transjunctions had been studied in extenso. (Kaehr, 1978, 2005)

In analogy and translation or transposition from the polycontextural to the semiotic topics, semiotic interactions between semiotic sub-systems shall be introduced. Semiotic sub-systems are a result of a decomposition of the semiotic matrix into its sub-systems. Such a decomposition is dynamic, depending on the complexity of the semiotic matrix. In this paper, only two cases are introduced. The decomposition into \( (2, 2) \)-subsystems, with \( S_1 = \{1, 2\} \), \( S_2 = \{2, 3\} \), \( S_3 = \{1, 3\} \).

And the decomposition into \( (3, 3) \)-subsystems of a polysemiotic system \( \text{Sem}^{(4,2)} \).

Nevertheless, a specific redundancy has to be repeated because of its established and deep-rooted sheepishness and stultifying ignorance. The more or less only answer or ‘feed-back’ I got, when I was emphasizing the importance of a number, e.g. 4, was, “Why an extension to 4 and not to 7 or 13 or 5112?” Nobody ever questioned the fact that their response is based on the number 2 (TWO). And surely I never privileged a single natural number of the established number system.

A criticism of such an idea of a privilege of a single natural number was perfectly done long before by Aristotle with his refutation of Pythagorean number theory. It seems to be better to live and to die with the number TWO than to question it. As far, it was an important scientific step by Peirce to introduce his triadic-trichotomic semiotics and first sketches to a trichotomic mathematics.

m-kontexturalen Zahlensysteme wird das wenig dialektische Moment der schlechten Unendlichkeit zugelassen.“ (Kaehr, Einschreiben in Zukunft, § 6, 1981)
Polycontextural and diamond dynamics

Sketches and exercises for dynamics and metamorphosis for formal systems

Rudolf Kaehr Dr.@
ThinkArt Lab Glasgow

Abstract

The Ancient Chinese idea of a permanently changing world in which stable formulations, i.e. axioms in logic, are obsolete is thematized by the polycontextural strategy of permanently changing complexity. As a framework to realize complexity change for formal systems the kenomic matrix is involved. Examples for such formal notations are given and exercises to learn more about polycontextural diamond systems are proposed.

1. Mediation in complex dynamic formal systems

It is said, that categories are distributed over the kenomic matrix. As pointed out, dissemination is composed of distribution and mediation. How is mediation working? Again, different contextures are mediated by their proemial relationship. That is, by the proemiality of their basic terms. What are the basic terms of categories? At first, it is mentioned that categories are build as compositions of morphisms. And morphisms are mappings with domains and codomains, conceived as objects. Hence, composition of two morphisms is ruled by the matching conditions of the codomains and domains of morphisms.

With such a proposition of the scenario, the pre-conditions of categories are not reflected. That is, there locatedness is left to the mental activities of the categorist.

How to find a mediation?

Therefore, the foremost step of distributed category theories, and not only distributed single categories, is to find possibility to encounter category theories at other loci in the kenomic grid, able to get into an interaction and getting mediated. On such a path, i.e. journey, categories might occur which are structurally not prepared for mediation. Hence, strategies have to be developed to find the adequate setting of categories or contextures and reflectional techniques might be applied to adapt automatically to the situation.

Most attempts to interact will fail. Some will succeed only partially, some, probably small systems, will succeed totally. All levels of possible interactions have to be accepted and studied.

Such a selection to find a winning mediation is not unfamiliar in the theory of formal systems. Formal systems are build on a syntactic selection, cut, between correct and non-correctly composed sign sequences. Here too, most sign sequences which are possible as combinations of the signs of the pre-given sign set (repertoire, alphabet) are not accepted as formulas. Hence, the accepted formulas are a small subset of the free monoid over the alphabet.
Mediators
"A new kind of interpreters appears to the programmer in ConTeXtures, the mediator-interpreter. This kind of interpreter has to collect, control and to establish the mediation of different programs written by different programmers at different locations at different times.

In contrast to existing compilers and interpreters with their hierarchic tectonics, the new situation can be defined as heterarchic. Heterarchic compilers/interpreters have to manage the mediation of the different hierarchic approaches of programming. This concept of heterarchic compilers opens up a new kind of societal collaborations.” (Kaehr, ConTeXtures, 2005)

Today, such a societal collaboration might be called Web 2.0 selection, compilation and interpretation. It might help to design the idea of a heterarchic Web Computing Paradigm which is not reduced to data or service sharing (cloud and grid computing). Mediation is not sharing but creation. Hence, a collective system production is not a collective sharing system but should be conceived as a genuine societal computing paradigm. This is not only intended to surpassing the deadly anachronism of Big Corporations but also the individualistic limitations of Open Source strategies.

2. A remainder from Chinese Ontology

"Traveler, there are no path. Path are made by walking." Antonio Machado

"A good mathematician is one who is good at expanding categories or kinds (tong lei)." 

The Chinese philosopher Jinmei Yuan has given some crucial hints to the understanding of ancient Chinese mathematical thinking:

Chinese mathematical art aims to clarify practical problems by examining their relations; it puts problems and answers in a system of mutual relation—a yin-yang structure for all the things in a changing world. The mutual relations are determined by the lei (kind), which represents a group of associations, and the lei (kind) is determined by certain kinds of mutual relations.

"Chinese logicians in ancient times presupposed no fixed order in the world. Things are changing all the time. If this is true, then universal rules that aim to represent fixed order in the world for all time are not possible." (Jinmei Yuan)

An Aperçu

Chinese ontology (cosmology) can be put into two main statements:
A. Everything in the world is changing.
B. The world, in which everything is changing, doesn't change.

This two main statements are designing a paradoxical constellation. Polycontexturality is complementing this ancient Chinese world model of harmony by dynamizing the concept of world-models:
C. A multitude of worlds are interplaying together.

The paradox to formulate mathematical rules in an ever changing world is very puzzling.

Many attempts to shed some light into it or even to solve the problem had been proposed.

It is not my intention to solve this ‘unsolvable’ problem.

Polycontextural logic attempts to formulate formal laws for an ever changing world. Nevertheless, we first have to abandon a Western interpretation of ‘change’. The Book of Change has nothing to do with Heraklit’s or Leibniz’s flux of things.
Many aspects about a philosophy of *logic and time* had been studied profoundly by the philosopher Gotthard Gunther. The connection of time and logic in polycontextural systems is not to confuse with any attempts of time or tense logics or physical time systems of any kind.

My own attempt to deal with the formal structure of changing first-order ontologies can be reduced, at this place, to two propositions:

**Strategies of change**

1. *Diamond strategies*: Each move is involved with its simultaneous counter-move.
2. *Complexity strategies*: Each move has to decide (elect/select) its intra-/trans-contextural continuation depending on the actual complexity encountered or created.

Intra-contextural continuation is supposing that the logic-structural complexity (of logic, arithmetic, semiotics, ontology) is stable and hasn’t changed, hence selects its next step.

Trans-contextural continuation has to reflect the possible change in complexity and has to chose, i.e. elect its contextures, i.e. its contextual environment for its next steps to select.

In classical arithmetics, the step from \( n \) to \( n+1 \) is unambiguously defined by the arithmetical rules or axioms. In contrast, polycontextural arithmetics is involved always, in at least, two actions, election and addition, producing a kind of a 2-dimensional tabular continuation:

<table>
<thead>
<tr>
<th>( m )-successor rule</th>
</tr>
</thead>
<tbody>
<tr>
<td>( n_{1.1} \rightarrow n_{1.1} + 1_{1.1} 1 )</td>
</tr>
<tr>
<td>( \rightarrow n_{1.1} + 1_{1.2} 1 )</td>
</tr>
<tr>
<td>( \rightarrow n_{1.1} + 2_{1.1} 1 )</td>
</tr>
<tr>
<td>( \rightarrow n_{1.1} + 2_{1.2} 1 )</td>
</tr>
</tbody>
</table>

Because the strategies of change happens on the most fundamental levels of formal systems (logic, arithmetic, mathematics, ontology, semiotics, computability) a real combination of the antagonistic features of permanent change and formal operativity is opened up and accessible to realization.

One mechanism to realize change is given by the proemiality or chiasm between intra-contextural ‘parts’ and trans-contextural ‘whole’. A predicate defined inside a contexture can become the criteria for a new contexture which is augmenting the complexity of the contextual constellation.

For the sake of simplicity, 3 constellations of change are considered:

a) *balanced* constellation between formalism and application, with equal complexity for the formalism and the system to be formalized: \( \text{compl}(\text{Form}) = \text{compl}(\text{System}) \),

b) *under-balanced* constellation, with \( \text{compl}(\text{Form}) \leq \text{compl}(\text{System}) \) and

c) *over-balanced* constellation, with \( \text{compl}(\text{Form}) \geq \text{compl}(\text{System}) \).

For classical Western thinking, based, shortly, on ontology and logic, only the balanced constellation with minimal complexity is available. Change is accessible in formal systems as change of complexion only. This strategy might be extremely sophisticated but it remains stable in respect to the logico-structural complexity of its paradigm.
Hence, not only every move (composition, concatenation, combination) in polycontextural diamond systems is accompanied by its hetero-morphic counter-movement but each movement is additionally determined by its polycontextural complexity-decision by election and selection.

In other words, in such a dynamic formalism, it easily can happen, that in the middle of a formal transformation (derivation, deduction, description, modeling) the complexity of the framework within those transformations happens might be changed, enlarged or reduced to legitimate a more reasonable and viable continuation of the transformations.

2.1. Exercises

2.1.1. Collect arguments - pros and cons, and beyond- and articles given in my Blog and elsewhere, which might support or reject the ‘Apercu’ of a Chinese Ontology and a Diamond World Model.

2.1.2. How are those thoughts connected to the project of Derrida’s Grammatology and the deconstruction of phono-logo-centrism in formal systems? Read and comment original texts only (if necessary translations)!

2.1.3. What can you learn from the sketches to a new rationality based on polycontexturality and the concept of Chinese scriptural paradigm for the understanding of the decline of the Western Hegemony?

2.1.4. What are the immanent limits of Western thinking and how might they influence the economic and financial crash? Connect your insights with the proposals given in my “The Logic of Bailout Strategies”.

2.1.5. Create more questions and answer of this kind.

2.1.6. A good exercise to experience the patterns and strategies of polycontextural and diamond thinking for more familiar topics, like ethics, human rights, identity, pluricentrism, Web 2.0 etc. might be the reading of the ‘exercises’ I have written in the collection “Short Studies 2008”.

All answers to the exercises can be written in English, German or French and posted to my Blogs. Chinese and Japanese proposals are welcomed.

3. Notational notes

3.1. The kenomic matrix

The kenomic matrix was introduced in ConTeXtures to offer a general notational approach to the dissemination of formal systems (logics, programming languages, semiotics) considering the modi of dissemination (identity, permutation, replication, iteration, bifurcation) as strategies to implement computability, reflectionability and interactionability into formal systems.

The term “kenomic” refers to keno, greek for empty. The matrices should be read as empty of logical and mathematical presumptions. That is, their mathematical features are not considered as important for the definition of the dissemination of formal systems. Such a reflection on the epistemological status the matrices would deserve a own contemplation. Metaphorically, matrices are not more than the naked shell of the turtle in the story of Lo Shu.

Hence, the kenomic matrix consists of empty places which might be occupied by formal systems or not. Like in kenogrammatics, kenoms are not linearly ordered but are inscribed in a tabular manner.
This openness allows to interpret kenomic matrixes naturally for reflectional and interactional constellations.

### 3.1.1. Computational, reflectional and interactional constellations

An empty kenomic matrix with \( m = 6, \ n = 3 \):

\[
\begin{bmatrix}
\bullet & \bullet & \bullet \\
\bullet & \bullet & \bullet \\
\bullet & \bullet & \bullet \\
\bullet & \bullet & \bullet \\
\bullet & \bullet & \bullet \\
\bullet & \bullet & \bullet \\
\end{bmatrix}
\]

Framed empty matrix for \( m = n = 3 \):

\[
\begin{bmatrix}
P & M & 0 & 1 & O_1 & O_2 & O_3 \\
M_1 & \phi & \phi & \phi \\
M_2 & \phi & \phi & \phi \\
M_3 & \phi & \phi & \phi \\
\end{bmatrix}
\]

**Reflectional matrix for \( \text{ref}_1 \) and \( \text{ref}_2 \):**

\[
\begin{bmatrix}
P & M & 0 & 1 & O_1 & O_2 & O_3 \\
M_1 & S_1 & \phi & \phi \\
M_2 & \phi & S_2 & S_3 \\
M_3 & \phi & \phi & S_3 \\
\end{bmatrix}
\]

**Interactional matrix for \( \text{inter}_2 \) and \( \text{inter}_3 \) on \( S_1 \):**

\[
\begin{bmatrix}
P & M & id, id & O_1 & O_2 & O_3 \\
M_1 & S_{1,1} & x & x \\
M_2 & S_{2,1} & S_{2,2} & x \\
M_3 & S_{3,1} & x & S_{3,3} \\
\end{bmatrix}
\]

### 3.1.2. Dissemination of logical particles

Regarding the sketched patterns for kenomic matrices as general place-holders for formal systems, applications for the distribution of the syntax of specific systems are following naturally. Distribution of logical connectors and quantifiers and their complex variables are constructed along the frame of the involved matrices.

### 3.2. Balanced formulas

As an example of the use of the matrix approach for composed formulas, the first-order formula for categorical composition might be involved.

\[ [c^3] : \text{mono-contextural composition} \]

\[ \forall x \forall y \left( \left( x \in \mathcal{E} \right) \implies \left( c(x) = c(y) \right) \right) \]

The short version of the formula in a 3-contextual situation, involving a transactional quantifier \( Q \), too, is given below. Such short versions, presented usually in a Guntherian context, are working only for very simple cases and are mostly misleading.
Hence, we have to take the burden and offer an explicit notation form of the formula. It is easy to understand the distribution of all elements involved: variables $x, y$, predicates $C, D, K$, quantifiers $\forall, \exists, Q$. The distribution of equality ($=$) is omitted.

$$\begin{align*}
\{C^3\} & : 3\text{-contextural, short} \\
Q^3 & = [Q^{3.2} Q^{3.1} Q^{3.3}] \\
\forall^2 & = \left[\forall^{2.2} \right]. \quad \exists^2 = \left[\exists^{2.2} \right]
\end{align*}$$

$$\begin{align*}
\{C^{3'}\} & : 3\text{-contextural, explicit} \\
\begin{pmatrix}
Q^{3.1} & \cdots & \cdots \\
\forall^{2.1} & \forall^{2.2} & \cdots \\
\exists^{2.1} & \exists^{2.2} & \cdots \\
\end{pmatrix}
\begin{pmatrix}
x^{1.2} & \cdots & \cdots \\
y^{1.2} & \cdots & \cdots \\
y^{1.3} & \cdots & \cdots \\
\end{pmatrix}
\begin{pmatrix}
C^{1.1} & \cdots & \cdots \\
D^{1.1} & \cdots & \cdots \\
K^{1.2} & \cdots & \cdots \\
\end{pmatrix}
\begin{pmatrix}
x^{2.1} & \cdots & \cdots \\
y^{2.1} & \cdots & \cdots \\
y^{2.2} & \cdots & \cdots \\
\end{pmatrix}
\begin{pmatrix}
x^{3.1} & \cdots & \cdots \\
y^{3.1} & \cdots & \cdots \\
y^{3.2} & \cdots & \cdots \\
\end{pmatrix}
\begin{pmatrix}
x^{4.1} & \cdots & \cdots \\
y^{4.1} & \cdots & \cdots \\
y^{4.2} & \cdots & \cdots \\
\end{pmatrix}
\begin{pmatrix}
x^{5.1} & \cdots & \cdots \\
y^{5.1} & \cdots & \cdots \\
y^{5.2} & \cdots & \cdots \\
\end{pmatrix}
\end{align*}$$
3.3. Non-balanced formulas

This is not the place to go in deeper details of polycontextural syntactic notational systems. It is easily to see that most of the combinatorial possibilities are not well-balanced. Again, such situations are not unusual, they appear in a much simpler combinatorics in classical formal systems too.
3.4. Exercises

3.4.1. Write an overview of typical notational constellations for balanced formulas. Use the sketches given in ConTextures and From Ruby to Rudy.

3.4.2. Program features of balanced \((m,n)\)-contextural notational systems for junctional, transjunctional connectors and quantifiers.

3.4.3. Try to define and program more efficient and ‘ergonomic’ notational approaches to general tabular syntactics.

4. Sketch for complexity changes

4.1. Extending constellations by accretion

Hence, e.g., a logical constellation as for table-a, with complexity \((3,3)\), can be changed to different tables depending on the type of the required complexity and complication with complexity \((3,4)\), \((4,3)\) and \((4,4)\). Such changes are involving the formal systems as a whole. An example for a change of complexity concerning the quantifiers only of polycontextural logics is given below.

\[
\begin{pmatrix}
\wedge^{1.1} & \ldots & \ldots \\
\wedge^{2.1} & \wedge^{2.2} & \ldots \\
\wedge^{3.1} & \ldots & \wedge^{3.3}
\end{pmatrix}
\begin{pmatrix}
\vdash^{1.1} & \ldots & \ldots \\
\vdash^{2.1} & \vdash^{2.2} & \ldots \\
\vdash^{3.1} & \ldots & \vdash^{3.3}
\end{pmatrix}
\]

Table - a

\[
\begin{pmatrix}
\begin{array}{ccc}
\land^{1.1} & \vdash^{1.1} & \vdash^{1.2} \\
\land^{2.2} & \vdash^{2.2} & \vdash^{2.3} \\
\land^{3.3} & \vdash^{3.3} & \vdash^{3.3}
\end{array}
\end{pmatrix}
\]

Table - b

4. Sketch for complexity changes

4.1. Extending constellations by accretion

Hence, e.g., a logical constellation as for table-a, with complexity \((3,3)\), can be changed to different tables depending on the type of the required complexity and complication with complexity \((3,4)\), \((4,3)\) and \((4,4)\). Such changes are involving the formal systems as a whole. An example for a change of complexity concerning the quantifiers only of polycontextural logics is given below.
4.2. Extending constellations by iterations and replications

Change for polycontextural systems has many faces. Additional to accretive extensions, a system might extend its scope by reflection into itself, self-reflection and introspection. This gets a formal representation by the super-operators \( \text{iter} \), for iteration and \( \text{repl} \), for replication.

- **Iteration** is augmenting complexity iteratively from \( S_i \) to \( S_{i+1} \).
- **Replication** is deepening complexity without augmentation from \( S_i \) to \( S_{i+1} \).

In the example, system \( S_2 \) is involved into iteration, leading from \( S_1 \) at \( (O_1 M_1) \) to \( S_2 \) at \( (O_2 M_2) \), and into replication, leading to \( S_{1,1,1,1} \) and \( S_{2,1,1,1} \).

**Formula notation**

\[
PM = \left( \text{id}_1 \left( \text{rep}_1 \text{rep}_1 \text{rep}_1 \text{rep}_1 \right), \text{iter}_1 \left( \text{rep}_1 \text{rep}_1 \text{rep}_1 \text{rep}_1 \right), x \right), \left( \text{iter}_2 \text{id}_2 \text{iter}_2, \left( x, \text{id}_3 \text{id}_3 \right) \right)
\]

**Table notation**

<table>
<thead>
<tr>
<th>PM</th>
<th>( D_1 )</th>
<th>( O_2 )</th>
<th>( O_3 )</th>
</tr>
</thead>
<tbody>
<tr>
<td>( M_1 )</td>
<td>( S_{1,1,1,1} )</td>

4.3. Exercises

4.3.1. Collect the arguments and constructions given in my articles and build a systematic model of the dynamic interplay of interactionality/reflectionality and interventionality in formal systems. Recommended articles: *ConTeXtures*, *Programming Dynamic Complexity*, *Godel’s Games, Actors and Objects*, *From Ruby to Rudy, How to compose?*

4.3.2. Compare those polycontextural and diamond models with models from modal logic, cognitive science, theory of reflection (Levebvre), reflectional programming (Smith, Maes) - and others.

4.3.3. Play around with your own ideas. Would it make fun to simulate polycontextural diamond dynamics with cellular automata models? What could we learn from such modeling, simulation and implementation? What would be lost?

4.3.4. Dynamics based on the ‘kenomic matrix’ might be studied for logical, arithmetical, categorical and semiotic systems by applying the materials proposed by now.

4.3.5. What are the structural consequences of contextual change for diamond category theory?

5. Metamorphic changes

5.1. Metamorphosis of topics

A transition from one contextual complexity to another doesn’t presuppose a pre-given existence of the new contextures. What might be presupposed is the possibility of change. And this possibility is realized by an application of the proemial mechanism between intra- and trans-contextural decisions.

An intra-contextural topic might become contextural prominence as a new contexture associated with the previous contextural constellation.

Reflection might change the meaning of an object by applying rules of chiastic metamorphosis.

Reflection is using the statement defining the object and this usage is defining the meaning of the object. Reflection and contemplation or introspection of an object can produce the insight that the meaning of the object under consideration is changing. Reflection as replication, thus, is augmenting the deepeness of the contextual
complexity by a replicative, self-thematizing way. Reflection as iteration, is augmenting contextual complexity by an iterative, self-reproducing way. Alternatively, a reflection could change to an interactional augmentation of the contextual complexity. Both together, reflecational and interactional changes, are defining replicative, iterative and accretive contextual complexity of a polycontextural system.

The example below shows that the beginning reflection is interpreting an object as the number zero belonging to the topic numerals. This situation is implemented in a 1-contextural programming language. A second reflection considers the same object not as a numeral but as nil belonging to the topic of lists. Reflection has not to come to an end and can go further and with the interpretation and might realize that the object can be understood as belonging to the topic Booleans and appearing as the truth-value true.

Therefore the introduced syntactical object in its neutrality, observed and represented by an “external observer” in log$_{3,3}$ is conceived as having simultaneously a numerical (in log$_{1,1}$), a symbolic (in log$_{1,2}$) and a Boolean (in log$_{1,3}$) meaning. Hence, there is a chain of metamorphic replication from the topic Numerals, Lists to Booleans and a notation of the ‘neutral’ syntactic object “object” of Syntax. It starts with a reflection of the object “zero” of Numerals, ends with the Boolean “true” and gets a contextual abstraction as syntactic “object” in Syntax.

The example is designed for reflectional poly-topics in the experimental programming language ConTextures.

```
<table>
<thead>
<tr>
<th>thematize (object, zero, nil, false)</th>
</tr>
</thead>
<tbody>
<tr>
<td>identify contexture$_{1}$1</td>
</tr>
<tr>
<td>define zero</td>
</tr>
<tr>
<td>lambda (f)</td>
</tr>
<tr>
<td>lambda(x)</td>
</tr>
<tr>
<td>x</td>
</tr>
<tr>
<td>refl. metamorph</td>
</tr>
<tr>
<td>identify contexture$_{1}$2</td>
</tr>
<tr>
<td>define nil</td>
</tr>
<tr>
<td>lambda(i)</td>
</tr>
<tr>
<td>true</td>
</tr>
<tr>
<td>identify contexture$_{1}$3</td>
</tr>
<tr>
<td>define false</td>
</tr>
<tr>
<td>lambda(a b)</td>
</tr>
<tr>
<td>b</td>
</tr>
</tbody>
</table>

Table notation
```

As the example shows, the reflectional distribution of the topics Number, List, Boolean, building the category “poly-topics”, is introduced as (zero, nil, false) at the locus O$_1$. Thematize (zero, nil, false) is distributed reflectionally over 3 places by the super-operator replication (repl) and neutrally represented by the syntactical object “object” at the place O$_3$. In this case, the positions at place O$_2$ remain empty.
Exchange relations:
- "define zero" is "define zero as zero", as the start of the levels.
  as: define zero in contexture1.1 as zero in contexture1.1
- "define nil" is "define zero as nil",
  as: define zero from contexture1.1 as nil in contexture1.2
- "define false" is "define nil as false".
  as: define nil from contexture1.2 as false in contexture1.3.

This change of identity of the topics from one contexture to another by reflection/replication is producing a chiastic chain guaranteeing the connectedness of the step-wise reflection of the whole. Levels and meta-levels of reflection are connected by means of proemiality realizing its structural rules of exchange, order and categorial correctness (coincidence).

Thus, define name is an abbreviation for "define name$_i$ as name$_j$" with $i=j$.

5.2. Exercises

5.2.1. Construct examples for reflectional, interactional and interventional constellations for poly-topics in the framework of ConTeXtures.

5.2.2. Construct further examples in the framework of ConTeXtures with topics like semiotics, logic, arithmetics.

5.2.3. Describe ‘empirical’ situations where such contextural changes of augmenting or reducing complexity seems to be unavoidable.

5.2.4. Try to develop a polycontextural measure for complexity.
Interpretations of the kenomic matrix

Exercises to the topics of Poly-Change

Rudolf Kaehr Dr.@
ThinkArt Lab Glasgow

Abstract
Examples for the exercises, § 5.2, of the recent article “Poly-Change” are given, concerning the logical, computational and semiotic interpretation of the kenomic matrix.
http://www.thinkartlab.com/pkl/lola/Polychange/Polychange.html

1. Exercises for matrices and brackets

1.1. Table and bracket notation for diagonal mxn-matrix

Table and bracket notation for diagonal 3 x3 – matrix

\[
\begin{bmatrix}
\hat{O}_1 \\
\hat{M}_1 & \hat{M}_2 & \hat{M}_3 \\
\hat{G}_{100}
\end{bmatrix}
\]

Table and bracket notation for diagonal 4 x4 – matrix

\[
\begin{bmatrix}
\hat{M}_1 \\
\hat{O}_1 & \hat{O}_2 & \hat{O}_3 \\
\hat{G}_{100}
\end{bmatrix}
\]

\[
\begin{bmatrix}
\hat{M}_2 \\
\hat{O}_1 & \hat{O}_2 & \hat{O}_3 \\
\hat{G}_{020}
\end{bmatrix}
\]

\[
\begin{bmatrix}
\hat{M}_3 \\
\hat{O}_1 & \hat{O}_2 & \hat{O}_3 \\
\hat{G}_{003}
\end{bmatrix}
\]
1.2. Reflection

Bracket notation for reflectional change from 3 x 3 to 5 x 3 matrix
Bracket notation for reflectional/replicational change from $3 \times 3$ to $3 \times 3$ matrix

\[
\begin{bmatrix}
O_1 \\
M_1 M_2 M_3 \\
\begin{bmatrix}
G_{110} \\
G_{110}
\end{bmatrix} \\
M_1 M_2 M_3 \\
\begin{bmatrix}
M_1 M_2 M_3 \\
G_{110}
\end{bmatrix}
\end{bmatrix}
\]

\[
\begin{bmatrix}
O_2 \\
M_1 M_2 M_3 \\
\begin{bmatrix}
G_{222} \\
G_{222}
\end{bmatrix} \\
M_1 M_2 M_3 \\
\begin{bmatrix}
G_{222} \\
G_{222}
\end{bmatrix}
\end{bmatrix}
\]

Bracket notation for reflectional/replicational change for $5 \times 3$

\[
\begin{bmatrix}
O_1 \\
M_1 M_2 M_3 M_4 M_5 \\
\begin{bmatrix}
G_{111.1.1.1} \\
G_{111.1.1.1}
\end{bmatrix} \\
M_1 M_2 M_3 M_4 M_5 \\
\begin{bmatrix}
M_1 M_2 M_3 M_4 M_5 \\
G_{111.1.1.1}
\end{bmatrix}
\end{bmatrix}
\]

\[
\begin{bmatrix}
O_2 \\
M_1 M_2 M_3 M_4 M_5 \\
\begin{bmatrix}
G_{22200} \\
G_{22200}
\end{bmatrix} \\
M_1 M_2 M_3 M_4 M_5 \\
\begin{bmatrix}
G_{22200} \\
G_{22200}
\end{bmatrix}
\end{bmatrix}
\]

\[
\begin{bmatrix}
O_3 \\
M_1 M_2 M_3 M_4 M_5 \\
\begin{bmatrix}
G_{03303} \\
G_{03303}
\end{bmatrix} \\
M_1 M_2 M_3 M_4 M_5 \\
\begin{bmatrix}
G_{03303} \\
G_{03303}
\end{bmatrix}
\end{bmatrix}
\]
1.3. Interaction

Alternative notation for reflectional / replicational change for 5 x3

\[
\begin{bmatrix}
O_1 \\
M^S \\
G_{1,1,1,1,1} \\
M^S \\
G_{10000} \\
M^S \\
G_{10110} \\
M^S \\
G_{10000} \\
M^S \\
G_{11111} \\
O_2 \\
M^S \\
G_{22200} \\
O_3 \\
M^S \\
G_{33300}
\end{bmatrix}
\]
Bracket notation for interactional change for 3 x 3

\[
\begin{bmatrix}
O_1 \\
G_{100} \\
M_1 M_2 M_3 \\
O_2 \\
M_1 M_2 M_3 \\
G_{020} \\
O_3 \\
M_1 M_2 M_3 \\
G_{003}
\end{bmatrix}
\]

Bracket notation for interactional and reflectional / replicational change to 3 x 3

\[
\begin{bmatrix}
O_1 \\
G_{110} \\
M_1 M_2 M_3 \\
G_{111} \\
M_1 M_2 M_3 \\
G_{111} \\
O_3 \\
M_1 M_2 M_3 \\
G_{003}
\end{bmatrix}
\]

Bracket notation for interactional and reflectional / replicational change to 4 x 5

\[
\begin{bmatrix}
O_1 & O_2 & O_3 & O_4 & O_5 \\
M_1 & S_{1,1,1} & - & - & S_{1,4} \\
M_2 & S_{5,1} & S_{2,2} & - & - \\
M_3 & S_{4,1} & - & S_{3,3} & - \\
M_4 & S_{3,1} & S_{2,4} & - & S_{4,4} & S_{4,5}
\end{bmatrix}
\]
1.4. Interplay between interactionality and reflectionality

Mixing freely reflectional and interactional pattern are leading to local iterations and recursions of the general scheme producing a fractalization of the general scheme.

The examples shows:

At the locus $O_2$ we have a full reflection $G_{222}$ and an interaction from the locus $O_1$ into the locus $O_2$ producing additionally to $G_{222}$ at $O_2$ the interactional pattern $G_{100}$ and an interaction from the locus $O_3$ into the locus $O_2$ producing the interactional pattern $G_{003}$.

Hence, the whole reflectional/interactional pattern of the example is: $[G_{111}, G_{222/003/100}, G_{033}]$. 
Interplay between interactionality, reflectionality and replicativity

Additional to the example above for interactionality and reflectionality, a pattern of replicativity or introspection is involved at O₁ with G₁,1,1,1,1 for M₁ and G₂,1,1,1,1 for M₂.

1.5. Permutations

Permutative patterns, produced by the super-operator perm, are behind those visits to other systems and back to the start again. The journey might start simultaneously in system₁ and system₃, both visiting system₂ at their offered locations, and back again. The table represents more the static pattern, while the bracket notation the dynamics
2. Logical interpretations

2.1. The kenomic matrix and polycontextural functions

The importance of the kenomic matrix for the interpretation and organization of polycontextural functions has to be emphasized. The classical treatment of polycontextural logical functions is based on set-theoretic functions and their decomposition, i.e. interpretation.

In this exercise of mapping logical systems onto the kenomic matrix, only bi-valent (dyadic, dichotomic, dual) logical systems are involved. As it is shown for semiotic systems, arbitrary contextural bases of dyadic, triadic and tetradic up to n-adic bases have to be considered. In the literature there is nearly nothing to read about the distribution mechanisms for genuine triadic m-contextural logical systems. First combinatorial concepts occur, nevertheless as early as 1962 in Na’s work.
### 2.1.1. Positions

Positioning or placing (Setzung), realized by the super-operator *id* (identity), is well studied in the polycontextural literature. But it is only applicable to a very small set of constellations. They have a natural interpretation by the main diagonal of the kenomic matrix, which is also producing the matching conditions MC.

Conjunctions and disjunctions as introduced by Gunther and their DeMorgan formulas are typical. But it is working for balanced negational systems only.

#### Super-operators for the mapping of logical systems onto the matrix

\[
\text{Logic}^{(n)}, \begin{bmatrix} \text{Logic}^{(n)} \end{bmatrix}_{\text{refl,act}} \xrightarrow{\text{sops}} \begin{bmatrix} \text{Logic}^{(n)} \end{bmatrix}_{\text{refl,act}}
\]

\[
\text{sops} = \{ \text{id}, \text{perm}, \text{red}, \text{bif}, \text{repl} \}
\]

\[
\text{id} : \forall i, j \in s(m): \quad \begin{bmatrix} \text{Logic}^{(i,j)} \end{bmatrix} \xrightarrow{\text{id}} \begin{bmatrix} \text{Logic}^{(i,j)} \end{bmatrix}
\]

\[
\text{perm}(i, j) : \forall i, j \in s(m): \quad \begin{bmatrix} \text{Logic}^{(i,j)} \end{bmatrix} \xrightarrow{\text{perm}} \begin{bmatrix} \text{Logic}^{(i,j)} \end{bmatrix}
\]

\[
\text{red}(i, j) : \forall i, j \in s(m): \quad \begin{bmatrix} \text{Logic}^{(i,j)} \end{bmatrix} \xrightarrow{\text{red}} \begin{bmatrix} \text{Logic}^{(i,j)} \end{bmatrix}
\]

\[
\text{bif}(i, j) : \forall i, j \in s(m): \quad \begin{bmatrix} \text{Logic}^{(i,j)} \end{bmatrix} \xrightarrow{\text{bif}} \begin{bmatrix} \text{Logic}^{(i,j)} \end{bmatrix}
\]

\[
\text{repl}(i, j) : \forall i, j \in s(m): \quad \begin{bmatrix} \text{Logic}^{(i,j)} \end{bmatrix} \xrightarrow{\text{repl}} \begin{bmatrix} \text{Logic}^{(i,j)} \end{bmatrix}
\]
2.1.2. Interactions

First concepts of logical interactions goes back to Gunther’s morphogrammatic transjunctions (1962).
2.1.3. Reflections

Reflectional patterns appeared first as interpretations of implicational constellations they might be modeled as reductions.

What’s the kenomic matrix for?
"It wasn’t unknown to Gunther that there is a little problem of distribution/mediation which needs a special explanation. Gunther’s solution insisted correctly that the value-sequence of sub-system S3 is still a disjunction because it is based in the morphogram [1] for disjunction. But it was slightly shifted to a value-sequences corresponding to a value-sequence of sub-system S1. To solve this point, an interpretation was introduced: it was called a disjunctive disjunction. Such interpretative solutions had been widely used to justify logical functions in place-valued logics. But they are in no way operational. In polylogical systems such problems are solved naturally by distribution over the polycontextural matrix."
2.1.4. Replications

Replicative constellations don’t have an appearance in polycontextural logics as it was sketched by Gunther. It seems that replications don’t have a direct representation in ‘propositional’ polycontextural logic. They might have a natural interpretation on a quantificational meta-level.

An example might be a ‘quotational’ system as a kind of intrinsic introspections. Represented as tables, replications are introducing an additional dimension to the 2-dimensional tabular structure.

3. Computational interpretations

3.1. General scheme of ConTeXtures

\[ \begin{align*}
\text{sketch} & \rightarrow \text{horizon}^{(x,y)} \\
\text{build} & \rightarrow \text{architectures} \\
\text{themarize} & \rightarrow \text{szenario} \\
\text{identify} & \rightarrow \text{contextures} \\
\text{define} & \rightarrow \text{operations} \\
\text{abstract} & \rightarrow \text{functions} \\
\text{propose} & \rightarrow \text{statements}
\end{align*} \]

3.2. Different modi of replication
Replication into the 'name-space' of a contexture

\[
\text{Matrix-Interpretations.nb file:///Volumes/KAE-TEXTE/KAE-TEXTS/Short%20Studies/Pub...}
\]

Replication of a name into a contexture

\[
\text{null}
\]
3.3. Mediators

"In a more generous setting the systems can be distributed over a network, say Internet, and mediators similar to compilers would have to mediate the distributed programming on mediated poly-processor computing systems. Mediators would have to parse the different programming approaches in respect to their mediability. That is, conditions of mediation would have to be checked, optimized and debugged. Thus, the chain of realization from programing to compiling has first to be augmented by a system of mediation. The new paradigm of realization now is programming-mediating-compiling in distributed and mediated programming languages."

4. Semiotic interpretations

4.1. Positions

Positioning (Setzung) semiotic systems isn’t well studied in the polycontextural literature. Nevertheless, semiotics, i.e. semiotic systems, like Peirce-Bense-Toth systems, might naturally be distributed and mediated over the kenomic matrix. Classical semiotics is distributed, per se, over a single kenomic locus which isn’t accessible to semiotics by semiotic means.

The examples for the exercises shows two sorts of modelings of the kenomic position matrix: a distribution of mediated semiotic dyads and a distribution of mediated semiotic triads.

In the first case, triadic-trichotomic semiotics, i.e. the matrix of sign classes, is understood as a mediation of dyads. The decomposition of the Peircean triads into...
mono-contextural dyads corresponds to the Bensean interpretation of semiotics and its semiotic Cartesian matrix.

Bense’s approach is not including a mediation of the dyads neither a contextural interpretation of the dyads. The dyads are composed by some set- or category theoretical operations. A mediative interpretation would automatically lead to a kind of a place-valued system for semiotics and inherit all its formal problems. Mediation of dyads in the sense of polycontexturality was introduced by my own papers and published recently at this place.

The second case is distributing and mediating full triads over the kenomic matrix. Hence, the mediation is concerned with triads and not with their internal structure, i.e. dyads, like the first example. This example of a different modeling, is mirrored by the different indexes involved.

**Epistemological cuts**
The decision to chose an epistemological paradigm of arbitrary complexity should be free. Unfortunately, there are only a few accessible. There is no special need to believe in dyads, triads tetrads, etc. or in monads. The question is, does it work? It works for dyads. It rarely works for triads. And there is no accepted formalism for tetrads. Obviously, n-adic relations of algebraic relation theory and relational logic are based on dyads, and their n-ads are always reducible to dyads. What’s lost with this manoeuvre isn’t told in general.

"To iterate is human ... but to recurse is divine." (Alfred Inselberg)

*Hence, to di(s)remit must be devilish?*

Therefore, it should be a question of a free decision to develop semiotics as founded in dyads, triads or tetrads, or generally in non-reducible n-ads.

To go further with this exercise, study the paper “Transjunctonal semiotics”.

**4.1.1. Triadic semiotics as mediations of dyads**

What does it mean to choose a triadic foundation of semiotics? As sketched before, triadicity as a mediation of dyads, hence, has to be realized on all levels of thematization. That is, a triadic matrix alone doesn't mean much if it is not based simultaneously on all needed triadic formal systems, like logics, arithmetic, category theory, etc.

On the other hand, the mechanism of mediation of dyads has not to stop with the construction of triads. All kind of n-ads, based on mediated dyads, might be constructed.
Table notation

\[
\begin{array}{cccc}
M & O_1 & O_2 & O_3 \\
M_1 & \text{Sem}_{1,1} & - & - \\
M_2 & - & \text{Sem}_{2,2} & - \\
M_3 & - & - & \text{Sem}_{3,3}
\end{array}
\]

Bracket notation

\[
\begin{bmatrix}
O_1 \\
M_1 M_2 M_3 \\
(\text{Sem}_{100})
\end{bmatrix}
\begin{bmatrix}
O_2 \\
M_1 M_2 M_3 \\
(\text{Sem}_{010})
\end{bmatrix}
\begin{bmatrix}
O_3 \\
M_1 M_2 M_3 \\
(\text{Sem}_{001})
\end{bmatrix}
\]
Scheme of $\text{Sem}^{(3,2)}$:

$$\text{Semiotics}^{(3,2)} = \begin{bmatrix}
(1.1)_{1.3} & (1.2)_{1} & (1.3)_{3} \\
\downarrow & \downarrow & \downarrow \\
(2.1)_{1} & (2.2)_{1,2} & (2.3)_{2} \\
\downarrow & \downarrow & \downarrow \\
(3.1)_{3} & (3.2)_{2} & (3.3)_{2,3}
\end{bmatrix}$$

Sub-system decomposition of $\text{Sem}^{(3,2)}$:

Sub-system$_1$ = \[
\begin{bmatrix}
(1.1) & (1.2) \\
\downarrow & \downarrow \\
(2.1) & (2.2)
\end{bmatrix}
\]

Sub-system$_2$ = \[
\begin{bmatrix}
(2.2) & (2.3) \\
\downarrow & \downarrow \\
(3.2) & (3.3)
\end{bmatrix}
\]

Sub-system$_3$ = \[
\begin{bmatrix}
(1.1) & (1.3) \\
\downarrow & \downarrow \\
(3.1) & (3.3)
\end{bmatrix}
\]

**Positions**

**3 – contextual semiotic matrix**

$$\text{Sem}^{(3,2)} = \begin{bmatrix}
\text{MM} & .1_{1.3} & .2_{1.2} & .3_{2,3} \\
1_{1.3} & 1.1_{1.3} & 1.2_{1} & 1.3_{3} \\
2_{1.2} & 2.1_{1} & 2.2_{1,2} & 2.3_{2} \\
3_{2,3} & 3.1_{3} & 3.2_{2} & 3.3_{2,3}
\end{bmatrix}$$

**Reflections**

**3 – contextual semiotic matrix [id., red., id.]**

$$\text{Sem}^{(3,2)}_{[\text{id., red., id.]}} = \begin{bmatrix}
\text{MM} & .1_{1.3} & .2_{1.2} & .3_{2,3} \\
1_{1.3} & 1.1_{1.3} & 1.2_{1} & 1.3_{3} \\
2_{1.2} & 2.1_{1} & 2.2_{1,1} & 1.2_{1} \\
3_{2,3} & 3.1_{3} & 2.1_{1} & 1.1_{1.3}
\end{bmatrix}$$
**Interactions**

\[
\text{3-contextual semiotic matrix \[\text{bif, id, id}\]} = \\
\begin{pmatrix}
1 & 1.1_{1.3} & 2.3_{2.3} & 1.3_3 \\
2 & 3.2_{2.3} & 2.2_{1.2} & 2.3_2 \\
3 & 3.1_3 & 3.2_2 & 3.3_{2.3}
\end{pmatrix}
\]

**Replications**

\[
\text{3-contextual semiotic matrix \[\text{repl, id, id}\]} = \\
\begin{pmatrix}
\text{MM} & 1.1_{1.3} & 2.1_{2.2} & 3.3_{2.3} \\
1.3_3 & 1.1_{1.1.3} & 1.2_{1.1} & 1.3_{1.3} \\
2.1_{2.2} & 2.1_{1.1} & 2.2_{1.1.2} & 2.3_2 \\
3.3_{2.3} & 3.1_{1.3} & 3.2_2 & 3.3_{2.3}
\end{pmatrix}
\]

### 4.1.2. Tetradic semiotics as mediations of dyads

**Positions**

\[
\text{4-contextual 2-semiotic matrix} = \\
\begin{pmatrix}
\text{MM} & 1 & 2 & 3 & 4 \\
1 & 1.1_{1.3} & 1.2_1 & 1.3_3 & 1.4_6 \\
2 & 2.1_1 & 2.2_{1.2.5} & 2.3_2 & 2.4_5 \\
3 & 3.1_3 & 3.2_2 & 3.3_{2.3.4} & 3.4_4 \\
4 & 4.1_6 & 4.2_5 & 4.3_4 & 4.4_{4.5.6}
\end{pmatrix}
\]

\[
\text{val(} \text{Sem}^{(4,1,2)} \times \text{Sem}^{(4,1,2)} \text{)} = \\
(1.1_{1.3} \times 2.1_{2.5} \times 3.2_{3.4} \times 4.4_{5.6}) \times (1.1_{1.3} \times 2.1_{2.5} \times 3.2_{3.4} \times 4.4_{5.6})
\]

with:

\[
\text{val(} \text{Sem}^1 \times \text{Sem}^1 \text{)} = (1, 2)_1 \times (1, 2)_1
\]

\[
\text{val(} \text{Sem}^2 \times \text{Sem}^2 \text{)} = (2, 3)_2 \times (2, 3)_2
\]

\[
\text{val(} \text{Sem}^3 \times \text{Sem}^3 \text{)} = (1, 3)_3 \times (1, 3)_3
\]

\[
\text{val(} \text{Sem}^4 \times \text{Sem}^4 \text{)} = (3, 4)_4 \times (3, 4)_4
\]

\[
\text{val(} \text{Sem}^5 \times \text{Sem}^5 \text{)} = (2, 4)_5 \times (2, 4)_5
\]

\[
\text{val(} \text{Sem}^6 \times \text{Sem}^6 \text{)} = (1, 4)_6 \times (1, 4)_6
\]

### 4.1.3. Pentadic semiotics as mediations of triads

As an example we shall study the mediation of two triadic-trichotomic semiotic basic systems, \text{Sem}^1 and \text{Sem}^2. Both semiotic systems are not decomposed into dyadic relations but kept together as triadic systems. A ‘concatenational’ composition of two genuine triadic systems results in a pentadic semiotic system as much as a ‘concatenational’ composition of dyads results in a composed triad.
With the composition formula:
\[ \text{compl}(\text{Sem}^{(5,3)}) = \text{compl}(\text{Sem}^1 \otimes \text{Sem}^2) = \text{compl}(\text{Sem}^1) + \text{compl}(\text{Sem}^2) - 1, \]
hence: \[3 + 3 - 1 = 5.\]

\[
\text{Sem}^1 = \begin{bmatrix}
1.1 & 1.2 & 1.3 \\
2.1 & 2.2 & 2.3 \\
3.1 & 3.2 & 3.3
\end{bmatrix}, \quad \text{Sem}^2 = \begin{bmatrix}
3.3 & 3.4 & 3.5 \\
4.3 & 4.4 & 4.5 \\
5.3 & 5.4 & 5.5
\end{bmatrix}
\]

\[
\text{Sem}^{(6,3,2)} = \begin{bmatrix}
\text{MM} & 1 & 2 & 3 & 4 & 5 \\
1 & 1.1 & 1.2 & 1.3 & 1.4 & 1.5 \\
2 & 2.1 & 2.2 & 2.3 & 2.4 & 2.5 \\
3 & 3.1 & 3.2 & 3.3 & 3.4 & 3.5 \\
4 & 4.1 & 4.2 & 4.3 & 4.4 & 4.5 \\
5 & 5.1 & 5.2 & 5.3 & 5.4 & 5.5
\end{bmatrix}
\]
The sub-system indices of the matrix values are omitted.

\[
\text{Partitions}_{(6,3)} = \left\{ \begin{array}{l}
(1, 2, 3), (3, 4, 5), \\
(1, 2, 4), (1, 2, 5), (1, 3, 4), (1, 3, 5), (1, 4, 5), \\
(2, 3, 4), (2, 3, 5), (2, 4, 5)
\end{array} \right\}
\]

**Sign class subsystems**

\[
\begin{align*}
\text{SR}^1 &= (1, 2, 3), & \text{SR}^2 &= (3, 4, 5), \\
\text{SR}^3 &= (1, 2, 4), & \text{SR}^4 &= (1, 2, 6), & \text{SR}^5 &= (1, 3, 4), & \text{SR}^6 &= (1, 3, 6), & \text{SR}^7 &= (1, 4, 5), \\
\text{SR}^8 &= (2, 3, 4), & \text{SR}^9 &= (2, 3, 5), & \text{SR}^{10} &= (2, 4, 5).
\end{align*}
\]

**Mediation Conditions MC**

\[
\text{MC}\left(\text{SR}^1 \otimes \text{SR}^2\right) = \{3.3_1 = 3.3_2\}
\]

\[
\text{MC}\left(\text{SR}^3 \otimes \text{SR}^4 \otimes \text{SR}^5 \otimes \text{SR}^6 \otimes \text{SR}^7\right) = \left\{ \begin{array}{l}
1.1_3 \equiv 1.1_4 \equiv 1.1_5 \equiv 1.1_6 \equiv 1.1_7,
4.4_3 \equiv 4.4_5, \\
5.5_4 \equiv 5.5_6 \equiv 5.5_7
\end{array} \right\}
\]

\[
\text{MC}\left(\text{SR}^8 \otimes \text{SR}^9 \otimes \text{SR}^{10}\right) = \left\{ \begin{array}{l}
2.2_8 = 2.2_9 = 2.2_{10},
5.5_9 \equiv 5.5_{10}, \\
4.4_9 = 4.4_3 = 4.4_5,
\end{array} \right\}
\]

\[
\text{MC}\left(\text{SR}^6\right) = \left\{ \begin{array}{l}
1.1_3 \equiv 1.1_4 \equiv 1.1_5 \equiv 1.1_6 \equiv 1.1_7,
2.2_3 = 2.2_9 = 2.2_{10}, \\
3.3_1 = 3.3_2,
4.4_3 = 4.4_5 = 4.4_8,
5.5_4 \equiv 5.5_6 \equiv 5.5_7 \equiv 5.5_{10}
\end{array} \right\}
\]
**Sub – system decomposition** (2 – sub – systems inherited, indices have to be adjusted)

\[
\begin{align*}
\text{SR}^1_{(1,2,3)} &= \begin{bmatrix}
(1.1)_{1,3} & (1.2)_{1} & (1.3)_{3} \\
\downarrow & x & \downarrow \\
(2.1)_{1} & (2.2)_{1,2} & (2.3)_{2} \\
\downarrow & x & \downarrow \\
(3.1)_{3} & (3.2)_{2} & (3.3)_{2,3} \\
\end{bmatrix} \\
\text{SR}^2_{(3,4,5)} &= \begin{bmatrix}
(3.3)_{1,3} & (3.4)_{1} & (3.5)_{3} \\
\downarrow & x & \downarrow \\
(4.3)_{1} & (4.4)_{1,2} & (4.5)_{2} \\
\downarrow & x & \downarrow \\
(5.3)_{3} & (5.4)_{2} & (5.5)_{2,3} \\
\end{bmatrix} \\
\text{SR}^3_{(1,2,4)} &= \begin{bmatrix}
(1.1)_{1,3} & (1.2)_{1} & (1.4)_{3} \\
\downarrow & x & \downarrow \\
(3.1)_{1} & (3.2)_{1,2} & (3.4)_{2} \\
\downarrow & x & \downarrow \\
(4.1)_{3} & (4.2)_{2} & (4.4)_{2,3} \\
\end{bmatrix} \\
\text{SR}^4_{(1,2,8)} &= \begin{bmatrix}
(1.1)_{1,3} & (1.2)_{1} & (1.5)_{3} \\
\downarrow & x & \downarrow \\
(2.1)_{1} & (2.2)_{1,2} & (2.5)_{2} \\
\downarrow & x & \downarrow \\
(5.1)_{3} & (5.2)_{2} & (5.5)_{2,3} \\
\end{bmatrix} \\
\text{SR}^5_{(1,3,4)} &= \begin{bmatrix}
(1.1)_{1,3} & (1.3)_{1} & (1.4)_{3} \\
\downarrow & x & \downarrow \\
(3.1)_{1} & (3.3)_{1,2} & (3.4)_{2} \\
\downarrow & x & \downarrow \\
(4.1)_{3} & (4.3)_{2} & (4.4)_{2,3} \\
\end{bmatrix} \\
\text{SR}^6_{(1,3,5)} &= \begin{bmatrix}
(1.1)_{1,3} & (1.3)_{1} & (1.5)_{3} \\
\downarrow & x & \downarrow \\
(3.1)_{1} & (3.3)_{1,2} & (3.5)_{2} \\
\downarrow & x & \downarrow \\
(5.1)_{3} & (5.3)_{2} & (5.5)_{2,3} \\
\end{bmatrix} \\
\text{SR}^7_{(1,4,5)} &= \begin{bmatrix}
(1.1)_{1,3} & (1.4)_{1} & (1.5)_{3} \\
\downarrow & x & \downarrow \\
(4.1)_{1} & (4.4)_{1,2} & (4.5)_{2} \\
\downarrow & x & \downarrow \\
(5.1)_{3} & (5.4)_{2} & (5.5)_{2,3} \\
\end{bmatrix}
\end{align*}
\]
Reduction of $\text{Sem}_2$ to $\text{Sem}_1$

\[
\text{red}(\text{Sem}^{(5,3,2)}) = \begin{bmatrix}
1 & 1 & 2 & 3 & 4 & 5 \\
1 & 1.1 & 1.2 & 1.3 & 1.4 & 1.5 \\
2 & 2.1 & 2.2 & 2.3 & 2.4 & 2.5 \\
3 & 3.1 & 3.2 & 3.3 & 3.2 & 1.3 \\
4 & 4.1 & 4.2 & 2.3 & 2.2 & 1.2 \\
5 & 5.1 & 5.2 & 3.1 & 2.1 & 1.1
\end{bmatrix}
\]

Replication of $\text{Sem}_1$ to $\text{Sem}_{1,1}$

\[
\text{repl}(\text{Sem}^{(5,3,2)}) = \begin{bmatrix}
1 & 1,1 & 2,1 & 3,1 & 4,1 & 5 \\
1 & 1.1,1 & 1.2,1 & 1.3,1 & 1.4 & 1.5 \\
2 & 2.1,1 & 2.2,1 & 2.3,1 & 2.4 & 2.5 \\
3 & 3.1,1 & 3.2,1 & 3.3,1 & 3.4,2 & 3.5,2 \\
4 & 4.1 & 4.2 & 4.3,2 & 4.4,2 & 4.5,2 \\
5 & 5.1 & 5.2 & 5.3,2 & 5.4,2 & 5.5,2
\end{bmatrix}
\]

Interaction between $\text{Sem}_2$ and $\text{Sem}_1$

\[
\text{inter}(\text{Sem}^{(5,3,2)}) = \begin{bmatrix}
1 & 1,1 & 2 & 3 & 4 & 5 \\
1 & 1.1,1 & 3.4,2 & 3.5,2 & 1.4 & 1.5 \\
2 & 3.4,2 & 2.2,1 & 2.3,1 & 2.4 & 2.5 \\
3 & 3.5,2 & 3.2,1 & 3.3,1 & 3.4,2 & 3.5,2 \\
4 & 4.1 & 4.2 & 3.4,2 & 4.4,2 & 4.5,2 \\
5 & 5.1 & 5.2 & 3.5,2 & 5.4,5 & 5.5,2
\end{bmatrix}
\]

4.1.4. What is the practical use of that fuss?

If there is any practical use for triadic-trichotomic semiotics, as Toth and others demonstrated in extenso, any extension of triadicity might open up some more complexity to deal with real-world matters in an operative and not reducing manner.

In sociology, cultural theory, international law, legitimations for torture and killing innocent people for good and accepted reasons, we encounter, in short, only two structural models of reasoning and acting. One is reducing complexity of what ever domain to a binary and dichotomic pattern. The other extreme is dissolving complexity into a multitude of autonomous isolated and not-mediated dichotomous systems.

The first has the advantage of maximal operativity in technological and juridical systems, supporting nearly fully-automated surveillance systems and killing procedures.
The second is hopelessly non-operative and still based on humanistic propaganda for a better world - and even for Change.

"The genius of Michelangelo is like the genius of the Talmud, with several layers of meaning, one on top of another. So you can interpret it in terms of Christianity and Judaism, sociologically, historically and artistically. We are just adding one level that has either been ignored or covered up over the centuries.” Cathryn Drake, Did Michelangelo Have a Hidden Agenda? http://online.wsj.com/article/SB122661765227326251.html

“For the third millennium, the struggle against semantic disorder and perversions of the intellect should supersede, precede and be sustained in all cultures, religions, systems of thought and political systems whenever there is a historical necessity to initiate a war of liberation from oppression, domination and exclusion.” Mohammed Arkoun, ISLAM: To reform or to subvert?, The rule of law and civil society in Muslim context, Beyond Dualist Thinking, 2006, p. 381

Hence, the academic question still remains: Wouldn’t it be worth to support a development of a cultural paradigm in which pluriversity and operativity could co-operate together?
The logic of bailout strategies

The end of capitalism or the end of the state?

Rudolf Kaehr Dr.

ThinkArt Lab Glasgow

Abstract

Some thoughts about/of the logic, blend, chiasm and diamond of bailout strategies. Eliciting aspects of the maxim: “Without insurrection, no resurrection”.

1. Duality, Blends, Chiasm or Diamonds?

”The end of the year is approaching” and “We are coming to the end of the year.”

"Notice that in the first, time is moving, while in the second the deictic reference point (conventionally called “ego”) is moving while time is fixed.” (J. Goguen)

Category

The category of approaching.

The concept of “approaching” is categorically closed. Compositions of “approaching” terms are producing composed “approaching”, and nothing else. Steps of approaching are building morphisms. Approaching morphisms are composable and are ruled by identity, commutativity and associativity. Hence, designing the category of “approaching”.

The category of coming.

The concept of “coming” is categorically closed. Compositions of “coming” terms are producing composed “comings”, and nothing else.

Dual to the category “approaching”, the category “becoming” is defined by the steps of approaching. “Becoming” morphisms are composable and are ruled by identity, commutativity and associativity. Hence, designing the category of “becoming”.

Duality and inversion

A dualism between “approaching”- and “coming”-terms might be constructed.

In another setting, between “approaching” and “coming” terms an inversion might be considered.

Dualism and inversion are categorically closed, too.

The dual or opposite of an “approaching” or a “coming” category is itself a category.

Thus, dualization and inversion are not unifying the concepts of “coming” and “approaching”, both concepts are left in alternating isolation.

Possible interactions of “approaching” and “coming” are tackled by the mechanisms of blending, chiasm and diamonds.

Blending

Blending (blend, mélange, mixture, integration) together “approaching” and “coming”.

This strategy is well introduced by Goguen’s “Semiotic Morphisms” approach to complex and polysemic systems. Blends are structured by categorical morphisms and composition.

Blending is conceptualized on the base of a single external observer for whom blending is offering a kind of a holistic unification of both tendencies, suggesting something new: a blend of both, here, with “coming” and
“approaching” mélanged together. But to add emergent features to the blending process, some ingredients have to be spent.

"Blending two conceptual spaces yields a new space that combines parts of the given spaces, and may also have emergent structure." (Goguen)

**Chiasm**
Chiastic inter-change of “approaching” and “coming”.
A chiastic interactive modeling is involving different points of view for different observers to describe the conceptual interaction between both as observer-depending.
What is “approaching” for one position is “coming” for the other position, and *vice versa*.
Both positions are aware about their inter-dependency. They are not observing in separation, each for itself, arbitrarily, different phenomena but a complexion of “movements”.

Chiasms, consisting of order, coincidence and exchange relations, are framing such inter-dependency.

Between “coming” and “approaching” a kind of an exchange relation, i.e. a duality happens.
The coincidence relation is guaranteeing a kind of “togetherness” of both categories, “coming” and “approaching”. It also gives the possibility of measuring their conceptual distance. And obviously, the objects of the categories “coming” and “approaching” are ruled, *per se*, by order relations, i.e. they are representing morphisms.

What is emerging as something new in the process of chiastic mediation is a complex phenomenon requiring different positions of observation to be recognized or constructed. The new is given by the features of the chiastic mechanism itself and not by any additional elements from the outside of the conceptual mechanism.

In contrast to blending, the processes involved in chiastic mediation retain their autonomy and are not mélanged together into a holistic wholeness, including elements from nowhere or left in isolation, like in the case of dualities and inversions.

**Diamond**
Diamond interplay of “approaching” and “coming”.
The diamond approach is liberating involved processes even more than the chiastic conceptualization, and is radicalizing the interactional approach of chiasms to an interplay between categorical and saltatorical systems.

Both conceptualizations, the categorical and the saltatorical, of a diamond are not only autonomous but are reflecting their antagonistic movements, i.e. they are involved in an antidromic and parallax interplay.

### 2. Bailout logic

*In economics, a bailout is an act of loaning or giving capital to a failing business in order to save it from bankruptcy, insolvency, or total liquidation and ruin.*

Detailed material and description about the complex aspects of the USA bailout is summarized at Emergency_Economic_Stabilization_Act_of_2008. Or watch the video: Why Won't The Bail Out Work?

There are funny discussions about the nature, probably it is better to call it, the ideology and stratagemes, of what’s going on today in the economic and financial world.
Without surprise, there is also an "illogic of the bailout": "Are the American people waiting for their own bailout? It's never going to come. You are the bailer, not the bailee. This is the biggest, fastest wealth-transfer scheme in the history of the world. And no one is marching on Washington. Explain this to me." (J. Farah)

**The Coming Global Insurrection**

But despite the propagandistic silence of the media, there is some uproar and insurgency globally to observe. To the global capitalism, its state doctrin and its cyclic collapse, a *global insurrection* is emerging out of suppression and ruins.

**Without insurrection, no resurrection.**

---

**On the level of debates**

The funniest chapter is the emergence of an ever growing *debate* about the transformation of the relationship between capital, economy, market on one side and state, governments, administrations, bureaucracy on the other side of this dichotomous distinction or antagonism.

Things are not as funny as they could be. The biggest economic crises since the last big crash is producing serious global poverty and will become a good reason for further wars.

What's annoying me is that the same stupidity of our ruler and their academic adviser is going on without any interruption or critical reflection on what happened and still is happening.

The same politicians and Nobel Prize Winners are on stage.

Do we have to enter this debate? There is no need to get messed up about their opinions. It seems to be good enough to think about the most simple structure of the whole manoeuvre to understand its logic and strategy.

The state, of whatever governmental form, from the Swiss democracy to Gordon Brown’s British surveillance administration, the USA to China, the state is asked for or is offering a *bail-out* of companies, corporations, institutions which are running into bankruptcy and other dysfunctionality.

The bail-out is paid by so called tax payers money. Hence, the state will take over such companies to some degree in ownership and regulations. It is seen as a reversal of the process of privatization. Some, are happy to interpret it as the symptoms of the end of capitalism. Unfortunately, the tax payers are not the players in this play. They are set into silence, by the state, the capital and their ideologues, parties and unions.

There are others, not many, for good reasons, which are more cynical and are understanding the bail-out
manoeuvre of the state as a coup of the capital to overtake the state with its tax payer's money and its power of regulation.

This position in the debate is still hidden in the background. It would be too dangerous to defend such a complementary position explicitly and with the proper intensity.

It is also not easy to conceptualize such a coup, because the categories of state and capital are getting involved into a transformation, which is beyond classical political theories and which is also transcending logical and dialectical understanding.

E.g., Gordon Brown, the British Prime Minster, a politician, who thinks from himself that he is saving the world, at least the Western world, with his programs of the Third Way, is becoming as politician a capitalist, overtaking banks and industries with the means of tax payers money. Meanwhile the heads of some Scotish banks, as capitalists, are becoming politicians in the banks ruled by the government.

The silencing of the voice of the people as consumers and workers is perfect. The ideologues of both sides are telling us, “Don't worry, it's only transitional and temporary. Everything will be back to normal, soon”.

It is said that the state will take shares of the companies and will use more control over them. Does it matter? There will be bankers and managers from the side of the capital who will enter the save heaven of governmental offices to do the job. Hence, the capitalist bankers are becoming administrators and the governmental administrators are becoming bankers.

The governmental bankers, which had been in charge to control the capitalist banks, are as much involved in the crash as their colleagues from the so called private sector.

Both positions of the debate, surely, are demanding for themselves unique truth of their interpretations. Only debaters with some secured positions are liberal or tolerant enough to accept, at least, the existence and relative reasonability of the complementary position. But that doesn't matter, now.

Hence, we are at the beginning, again. The crisis is declared as much too serious to allow the luxury of philosophical reflections and distinctions and is only weakening, argumentatively, the severity of the global situation.

In fact, there is, up to now, no debate at all. The opposite position to ones position in this virtual debate is declared as mislead and for empirical and logical reasons as wrong.

It is still the dominating position that the government has to save the failing industries (banks, car, insurance, etc.) with the help of bailout strategies. But it is only consistent, and is in fact on the way to happen, that the state is offering itself a bailout to survive.

In other words, the bailout strategies to save the economy will be applied to save the administration, military, police, and all the surveillance and controlling institutions of Web2.0 and the building industry to build more prisons.

The government declares, it will use the tax payers money properly, fulfilling highest standards of economical thinking and ethics. But who in the government is, by definition, able to do this honorable job? Nobody else than bankers have by profession the knowledge and experience to be able to such a capitalist job. Hence, the bankers are in the government and are controlling the state banks.

Does it matter, where the money comes from, directly from the national tax payer or indirectly, via China e.g.? The government wasn't elected to spend this money especially for bailouts, anyway.

Supposed distinctions:
private/public,
state/capital
market/company
state/economy
administration/democracy

Is the tax payers money private or public?
Is a tax payer private? What happens if the so called worker is his own capitalist? A shareholder of “his” company for which he is now on the way to pay his bailout with the generous help of the government? And the capitalist, e.g. the manager his own (self-)exploiter?
Hence, the tax payer is paying the bailout of his company where he is a shareholder and a worker at once, which is exploiting him and makes him, at the same time, an owner of the company, which is, together with him, on the way to bankruptcy. This surely has to be prevented, otherwise the tax payer gets unemployed and is losing his status as a shareholder and as a worker of his company.

It also has to be prevented because the tax payer could start a rebellion against the whole system, paid on the base of his private money he put aside. But how could he, and where?

There are no capitalists nor workers, anymore. Both are intertwined into the complex reality of globalization and the self-exploitation by anonymous corporations.

That is, public money from the private tax payer has to save the private company owned by the capital. The state wants to become a part-owner of the capital with the money of the private shareholders of the company. The mission is to save employment for the private shareholders. This sounds humanitarian and is in harmony with a progressive protestant work ethic.

*But this is only one side of the coin.*

Is it not better for the public capital and the markets to get as much capital by the state's private capital to be fit to survive against the consequences of mismanagement and global competition?

In fact, and this will become, in the future, more and more obvious, the capital has to be made fit against the cultural limitations of Western science and technology and their decline.

The so called nationalization of markets is in fact a disguised overtaking of the state by the capital.

The state, complementary, is hallucinating a control and annexation of the markets and the capital. He wants to become owner of the banks, etc.

The bailout *"Promotes centralized bureaucracy by allowing government powers to choose the terms of the bailout."* (WiKi)

The state is playing the rescuer of the markets to save its own existence.

The capital is overtaking in disguise the state to save its own existence.

Therefore, the whole bailout saga is a secret *coup: coup d’état and coup de capitale.*

The common of both is the commotion and the threat of their proper existence.

Both forms of existence are fundamentally out of date and obsolete.

The epistemological problem is:

The (bailout) situation is polycontextural and self-referential, and our mathematical and computational paradigms, ideologies and tools are mono-contextural and linear.

3. **Neither nationalization nor privatization**

3.1. **The Big Joke of the Third Way**

The Big Joke of the Third Way is: Who is overtaking whom?

Circular situations should be read in both directions.

Hence, the "withering away of the state" (Lenin)\(^6\) has to go *"hand in hand"* with its inverse movement of a dissolution of the capital.

3.1.1. **Bailout of the capital**

The state is supporting the capital.

The capital is using the state's capital.

The government is governmentalizing the capital.

The capital is capitalizing the state.
CSSC:
Nationalization: capital --> state
Privatization: state --> capital.

Der Staat unterstützt Banken (Verstaatlichung des Kapitals).
Die Banken bedienen sich des Staates. (Verkapitalisierung des Staates)

3.1.2. Bailout of the state

The state is using the capital's capital.
The capital is supporting the state.

The state is governmentalizing the capital.
The capital is capitalizing the state.

SCCS:
Governmentalization: state --> capital
Capitalization: capital --> state.

3.2. Blending of bailout

The blending interpretation of the bailout is blinding for the fact that the emergent features of whatever mélange between capital and state has first to be generated and paid.
But a blending approach, with its undecided mix, is best prepared to offer the necessary structural vagueness and non-transparency for ever growing new departments in the opacity of both administrations, the state and the capital.

3.3. Chiasm of bailout

Inter-dependencies of both, capital and state, still intertwined and reciprocatively dependent, but at least a holistic and processual conceptualization and understanding of the mechanism is uncovered and conceived by the chiastic thematization of the bailout.

The chiastic approach of the bailout is emphasizing the complicity of both movements, the privatization and the nationalization, as belonging to the same reality.

Hence, any controversial debate, like with the logical, contradictorily or antagonistic, modeling, which is understanding the parts as singular or in a reflective turn as dual, is obsolete within the chiastic understanding.

What has to be studied is the inter-relational complicity of both interpretations, their chiastic relationality, like the coincidence and exchange relations. To function as a whole of interdependency, the exchange
relations between the opposite, but common terms have to be adapted by the coincidence relations between
the similar but distributed terms.

The dualistic interpretation of the situation is conflictive and is not offering a tribune for negotiation. One,
and only one interpretation is accepted by the defenders as adequate and true. On the base of such blindness,
only ethical and moralizing judgements and the cry for more interventional actions are available.

The chiastic interpretation is offering an insight into the very mechanism of the conflictive situations. The
mediating contexts of the chiasm is placing the structural possibility of negotiation and resolution, albeit
inside of the framework of the scenario.

Both positions, the dualistic and the chiastic, are accepting the situation as it is. This is reasonable for
descriptive and analytical motives. Despite its non-classical conceptuality, the chiastic model is not yet
offering any structural strategies to overcome and reject the structural fundaments of the whole situation.

As a result, a kind of a humanitarian harmony of the antagonism remains as the ultimate aim. This solution
of the problem is guaranteeing a safe return of the problem on a new, more complex and reflected level of
development, securing an even deeper and broader stage-management of the "eternal recurrence" of booms,
bubbles and crashes.

### 3.4. Diamond of bailout

The diamond approach is not denying the correctness of the chiastic modeling of the antagonistic situation
but is trying to reject the whole construction in favor of a future-oriented transformation, where the
components or “objects” of the chiasm, state and capital, are dissolved.

The diamond approach, with its complementarity of acceptional and rejectional thematizations, is separating
the antagonistic aspects from their intertwining complicity. Both are conceived as autonomous societal
movements, crossing at some parts, historically, and disappearing into other situational interactions.

Their complicity is historic and there is no necessity to reduce social life to it.

Because of the autonomic interplay between acceptional tendencies, framed by categories and rejectional
tendencies, framed by saltatories, a chance to separate both structurations (of societal structures and
movements) is conceived and accessible to realize.

### 3.5. The bailout of the bailout

Rejection of the figure of bailouts by dissemination and subversion.

The bailout of banks and industries by the governments is a big sandbox game: moving money, power and
control from one societal heap to another societal heap of a national and/or global economy framed by the
opposition of capital and state.

#### 3.5.1. Dissemination: Polycontexturality of society

Polycontexturality of society is dissolving such terminological identifications like ‘state’ and
‘capital’. Terms, like ‘state’ and ‘capital’, are not observer-independent identifications, like
‘potato’ or ‘herring’. They are depending on observations and are set into multiple
perspectives, which are dissolving their a-historical and nominalistic identity.

Polycontextural logics are prepared to describe, formalize and implement such complexities
in an adequate way.

Gunther Teubner is describing the challenges for law and society and its understanding by
polycontextural thematizations.

"In Habermas’ “ideal speech situation”, formal procedures are supposed to guarantee the undistorted reciprocal
expression of individual interests as well as their universalization into morally just norms. However,
polycontexturality, one of the most disturbing experiences of our times, thoroughly discards these recent variations of a
Kantian concept of justice.

"With polycontexturality understood as the emergence of highly fragmented intermediary social structures based on
binary distinctions, society can no longer be thought of as directly resulting from individual interactions, and justice can no longer be plausibly based on universalizing the principle of reciprocity between individuals."

"In these perspectives, irreconcilable incompatibilities result from colliding social practices each of them endowed with their own rationality and normativity and with an enormous potential for mutually-inflicted damage.

The highest degree of abstraction has been reached by Gotthard Günther who radicalizes polycentricity into a more threatening polycontexturality, that is, a plurality of mutually exclusive perspectives which are constituted by binary distinctions. They are not compatible with one another and can be overcome only by rejection values which in their turn lead to nothing but to different binary distinctions." (Teubner, p. 4/5)

3.5.2. Subversion: Morphogrammatics of sociality

A morphogrammatic subversion of the understanding of society is rejecting their leading concepts and models of monetary and phono-logical interpretations.

Subversion, hence is not rejection “which in their turn lead to nothing but to different binary distinctions.” Binary distinctions discovered by rejections are establishing, again, contextures albeit new ones, and thus there is, in this strategy, no escape and nothing left except of contextures, and contextures of contextures.

There is not much to tell about such a morphogrammatic turn or abstraction, i.e. subversion, and it is hard to write and to inscribe how to subvert the surface structures of society to 'enlight' its hidden actional structuration by morphogrammatics.

Morphogrammatics is abstracting even from “the highest abstraction” (Teubner) of the contexts of polycontexturality.

To try it with metaphors, it seems to be reasonable, in what ever logic or rationality, that contextures too, are taking place, are positioned and localized, where?, in a kind of space(s). Such a space might be called an inscriptional space or even more metaphorically a (meta-/proto)conceptual space, giving space and loci for éspacement (spacing) and temporalisation of positioned contextures and their interplay. Such a space is empty of all kinds of conceptual characterizations but it is nevertheless not a vague void, but structured, organized, beyond the dictatorship of order and chaos, axioms and rules.

That bailouts for state and capital can happen in a specific societal space, which has to be spaced and temporalized by actions and activities before/after capital and state can happen on/off historical stage of history. Bailouts to save living space and future(s) have to be discovered and invented beyond state and capital - and bailouts.

Without fundamental change(s) nothing will be changed for the future.

XANADU’s textemes

Diamond theoretical reflections on hypertextuality

Rudolf Kaehr Dr.@
ThinkArt Lab Glasgow

Abstract

Xanadu is still not yet realized. Nevertheless, it is appropriate, not only to understand its principles and its radical difference to established Web hypertext and multimedia, but to try to think and design even more advanced concepts of non-traditional interactions. One interesting extension of identity-oriented thematizations is opened up by polycontextural, kenogrammatic and diamond approaches to text theory; proposed recently as textemes (or textems). Textemes are based on the interplay of anchored semiotic diamonds and are delivering necessary environments for transclusions. Transclusions and transjunctions are modeled additionally in a polycontextural setting. The characteristics of ‘electronic’ text in contrast to ‘physical’ paper texts are emphasized.

1. Xanadu: Nelson’s still new principles

1.1. Hyper-textuality

Since some decades, everybody knows Xanadu and nearly nobody ever has seen it working. Most people think of it as a special kind of a hypertext project with two-way links and connected with projects like Hypercard. Hence, the focus is on the machinery of links.

Personally I had a similar perception and therefore wasn’t specially interested in it. But there is a very crucial distinction at place which makes a profound difference to all kind of linking systems. It is Nelson’s insistence on the difference of ‘physical’ and ‘electronic’ documents. At the first glance this seems to be obvious and trivial too, but it isn’t at all.

There is a lot of postmodern writing about the virtuality and simulacrum of electronic media. Nevertheless I couldn’t find any conceptually and technically useful elaborations.

With such a change, from the ‘physical’ to the ‘electronic’, in the ontological and epistemological status of documents and texts, the whole topic of links (transclusions, deep links, content links, etc.) appears as a ‘natural’ consequence of the new understanding of text (‘electronic’, digital’, ‘virtual’). Quite obviously, the term ‘electronic’ is historic and utterly metaphorical. Xanalogical concepts are not about electronics, information processing, etc., neither about ‘virtuality’.

A good example for a conservative and common understanding of the Web and its hypertext links is demonstrated with Michael Wesch’s “The Machine is using Us” Youtube entry.

http://mediatedcultures.net/ksudigg/?p=78

"Digital hypertext is above all... hypertext can link..."
"Digital text can do it better. Form and content can be separated."
"XML was designed to do just that."
1.1.1. Ted Nelson’s Xanadu

"To Project Xanadu, that means enacting two types of connection: profuse and unbreakable *deep links* to embody the arbitrary connections that may be made by many authors throughout the world (content links); and *a system of visible, principled re-use*, showing the origins and context of quotations, excerpts and anthologized materials, and content transiting between versions (transclusions).

This may be simplified to: connections between things which are *different*, and connections between things which are *the same*. They must be implemented differently and orthogonally, in order that linked materials may be transcluded and vice versa. This double structure of abstracted literary connection -- *content links* and *transclusion* -- constitute xanalogical structure.”

Transclusion

"Transclusion is what quotation, copying and cross-referencing merely attempt: they are ways that people have had to *imitate* transclusion, which is the true abstract relationship that paper cannot show. Transclusions are not copies and they are not instances, but *the same thing knowably and visibly in more than once place*. This is a simple point which is remarkably difficult to get across. While copies and cross-reference are workarounds in place of transclusion, aliases and caches are *forms* of transclusion.”

Text is not simply text

"Nelson always meant hypermedia when he said hypertext, it's one of the things that people get wrong about Nelson. They think that they've invented hypermedia and he only invented hypertext. He meant ‘text’ in the sense of corpus, not text in the sense of characters. I know this for a fact because we've talked about it many times (van Dam 1999, interview).”

Hypertextuality in the sense of the Web and its WEB-0.X-mythology, is restricted to a unidirectional exchange of signs as data without environments. Web links are not only uni-directional by definition but they have only two logical states: broken/unbroken.

It would by great to enjoy a more dynamic bi-directional Web connectivity in the sense of transclusions (Ted Nelson). But Xanadu links are postulated as UNBREAKABLE. Does it matter if they are one- or two-way links if they are not qualified to *perish*?

http://www.xanadu.com/xuTheModel/

What’s an ‘electronic’ text?

It isn’t easy to characterize properly ‘electronic’ or ‘digital’ texts and documents in the sense of Nelson’s intentions.

A digital text in the common sense is easy defined. It is a digitally codified mapping of a text (media) by a binary code into an electronic representation. This is realized for all media (text, sound, picture, graphics, etc.).

One hint to understand the difference to the common understanding of hypertext is given by the distinction of “same” and “different” instead of ‘equal’ and ‘unequal’ of textual ‘things’. 

"... connections between things which are *different*, and connections between things which are *the same*."

A further hint to the different epistemological character of ‘electronic’ texts is given by the necessity of ‘orthogonal’ structures. "They must be implemented differently and orthogonally, in order that linked materials may be transcluded and vice versa.”

Furthermore, ‘electronic’ texts are characterized by a complementarity of polar distinctions, i.e. by a double structure of ‘content links’ and ‘transclusions’.

"This double structure of abstracted literary connection -- *content links* and *transclusion* -- constitute xanalogical structure.”

Some more distinctions

Some more distinctions might help to grasp the specific character of ‘electronic’ texts.

1. The mainstream understanding of text is still dominated by the sentence-model. A text is a composition of sentences (phrases, statements, etc.). A sentence is ideally a well-formed statement with a clear meaning.

2. Hypertext in the mainstream understanding is a text of a text. As a meta-level a markup
language is constructed to link textual elements of the primary text.

"In a classical node-link hypertext, a graph can be constructed on the set of nodes where each edge is identified with a link and structure discussions typically take place with respect to this graph." (Neumuller, p. 89)

"The Web link is in essence little more than a goto or a jump instruction to the Web browser to retrieve and display a new document." (ibd., p. 149)

3. And to give the whole thing some meaning, a markup language of a markup language of the ordinary text is introduced. This is the concept of a multi-layered text, which still remains syntactically restricted, is introduced in an ontology-based Semantic Web.

"...transclusions are hard to formalize in graph theory: are they nodes themselves? If they are, they would transform trees into directed graphs. I have included them in this section, as they seem to mark a breakpoint of graph theory." (ibd., p. 90)

The same at different places, without ‘physical’ representation by copy-and-paste.

"Transclusions are not copies and they are not instances, but 'the same thing knowably and visibly in more than one place.'" (Nelson)

**Key Concepts**
- Parallel Documents
- The Big three : Transpointing, Transclusion and Transcopyright.
- Transpublishing.

Hence a further aspect of the epistemology of 'electronic' texts, i.e. xanalogical texts, is the fact that they have to be placed, that they have to take place in a textual space. There is no such thing in classical text theory as a textual place or locus. In other words, classical texts are anchored in uniqueness, hence the unique anchor can be lifted and omitted. A procedure which is producing specific speculations, illusions and phantasm about otherness, void and omnipotence. This observation of a missing localization of classical textuality shouldn’t be confused with the triviality that in classical text theory all kinds of topologies, hodologies and super-graphs might be used to explain, model and formalize classical texts as complex objects.

In more recent publications at the University of Southhampton, Nelson introduced further distinctions and broader self-interpretations.

The concept of anchored semiotics, diamonds and textemes offers a simple but radical mechanism of epistemic localizations of documents.

**Table of concepts**

```
[ (linear)text  sentences  first-order logic
hypertext           marked sentences  modal logic, graph theory
semantic hypertext  2-level marked texts  higher-order modal logic
xanalogical docuverse  transclusions  transpointing ?? ?
```

Nevertheless it seems therefore that, despite the contrary narratives, the idea of Xanadu in itself is strictly different, not only from established hypertext systems but also from Vannevar Bush's Memex.

Because elaborated conceptuality is missing, the whole Xanadu projects seems to be lost in metaphors and intentions.

**Founding background**

Behind many of the most important inventions in computer technology, realized or
conceptualized, by Doug Engelhart, Ted Nelson, Heinz von Foerster and Gotthard Gunther, was the enthusiastic help of the assistant of Harold Wooster, Rowena Swanson, of the US Air Force Office of Scientific Research.

"Long ago we considered on-line documents. One of the first questions we asked was: "How can computers improve on paper documents?" Our principal answer: "By keeping every quotation connected to its source." We still believe this. However, those who created today's computer world didn't get that documents should be different now. They imitated paper. We see this as retrograde, like the buggy-chip soxets on the early horseless carriates." (Ted Nelson) 

What exactly does it mean: "keeping quotations connected" to it's sources, if there are no sources but only quotations?

Perishing links and textemes
Perishing links are neither breakable nor unbreakable, they are enabling such differences, uni- and pluri-directional. Hence, a perishing link is not a killed link. And an non-perishing link is not an endless link, like an endless non-terminating process. Because of the polycontextural complexity of the xanalogical link structures, with its chiasm of 'originals' and 'copies', a broken (micro-)link is not breaking the link as such. Redundancy, self-repair and learning is included in the conceptuality of complex links, i.e. interactions.

Textemes with their environments and chiastic interactions are enabling links to perish, to be, as reductions, ordinary links, which might be broken/unbroken or even unbreakable. Nevertheless, actions in textemes and between textemes are not links but interactions, able of interactionality, reflectonality and interventionality. Hence, they have their life.

Hypertextuality in the sense of Xanadu might find a scientific model by the interplay of internal and external environments of textemes. That is, links refer to the external environment and are connected with the internal environment of neighboring textemes, and vice versa.

Common understanding of links
"Let us now try to use those notions for analysing the main features of Web pages. Web pages are so-called hypertexts, that is, texts with some of their components (words or sentences), possibly linked to other (hyper)texts, and so on and so forth. The reader can navigate through the whole text in a non-linear manner, by activating so-called hot links or anchor points that are linking some piece of text to some other.

These links are an obvious example of indexes, with a word pointing to (referring to) its definition or to some related piece of information. The WWW merely extends the basic notions of hypertext by making it possible for one index to refer to some physically-distant location on a remote computer somewhere else on the Internet, together, of course, with the ability to link to and therefore communicate images and sound. However in order to act as an index, a sign has to be recognized as such, i.e. the index has to exhibit itself as a reference. This is done in hypertext by marking the hot links in blue ink, in order to make the reader aware that he can jump to another piece of hypertext or image, therefore using a conventional symbol in order to "show" the index as such." Philippe Codognet, THE SEMIOTICS OF THE WEB, http://pauillac.inria.fr/~codognet/web.html

1.2. Xanadu and XML

Is there any chance to realize the Xanadu document concept in the framework of XML? I would like to stipulate that this question has to be connected with the problem of identification. Identification is basic on all levels of computation (Lambda Calculus) and understanding (naming). XML is strictly restricted to identity; and as a consequence to hierarchy.

It would be an artificial and tedius project to model, formalize and to try to realize the specifics of Xanadu in the framework and language of XML. But there are people who found a fundation for that.

Obviously, Xanadu's link concept, especially the "two-way links" are not part of the Web-link nomenclatura simply because Web links are linking identifiable documents together in different modes, e.g. direct, indirect, reciprocal, one-way, multi-way, and even incestuous, over- and under-linking, etc.

XML simulations of Xanadu

Academic implementations of Xanadu as simulation are presented at some universities. As long as simulation is not confused with realization nothing is wrong about such achievements and much can be learned. XML is
modeled along the ‘physical’ concept of documents. Hence, a construction of genuine xanalogical concepts with XML methods is not producing more than a simulation instead a realization. As much as any simulation of an earthquake isn’t the real earthquake, a simulation of Xanadu concepts isn’t the real thing. Presupposed, obviously, there exists as such a thing.

"With the XML Pointer Language (XPointer) fragments of XML documents can be identified and addressed as well. Thus, a combination of XML, XLink and XPointer can be employed."

Josef Kolbitsch, Hermann Maurer, Transclusions in an HTML-Based Environment

1.2.1. Abstractness of documents

The great step of Xanadu seems to not be primarily in the new modes of linkage but in the radically new and more abstract concept of an "electronic document or text", positioned conceptually on a very different epistemological level than, say XML-documents which are represented as syntactical trees. And thus, on the base of this new abstraction of textuality from the physical to the 'electronical', a transformation of the ordinary link concepts follows ‘naturally’.

"Like Engelbart, Nelson believes the technical system moves in paradigms, and that the current era is bound to paper as a central metaphor. We need to be forced from our collective tricycles. 'I deal with new paradigms' (Nelson 1999, interview)." (Belinda Barnet)

On the base of the classical ‘electronic document’ concept, mirroring the main characteristica of physical texts (text, sound, graphis, pictures, odeurs, haptics, etc.) only a specific kind of links are possible.

"The term multi-way simply refers to the fact that the link exchange is between 3 or more websites, however each link is singular by only pointing to one other website."

"A typed link in a hypertext system is a link to another document or part of a document that includes information about the character of the link."

"Nelson coined the term "transclusion." as well as "hypertext" and "hypermedia", in his 1982 book, Literary Machines. Part of his proposal was the idea that micropayments could be automatically exacted from the reader for all the text, no matter how many snippets of content are taken from various places".

"In computer science, transclusion is the inclusion of part of a document into another document by reference. It is a feature of substitution templates." (WiKi, transclusion)

Different identity relations

"Let me talk identity relationships. The term identic you might enjoy looking up in the dictionary. I hope it does not have some mathematical definition. I am just trying use it here to mean some relationship showing the two data structures are the same.

The number of different identity relationships in the computer field. A copy is in identic relationship with its original. An instance is in identic relationship with its original. A cached copy is in identic relationship with its original. A counted reference is in identic relationship with the places, the context, that reference it. So these are different identic relationships with different properties. Write-through cache, write-back cache.

So now I want to tell you about another identity relationship. I am calling it transclusion. Think of it as hypersharing if you like. What it is is this. There is only one copy, one master copy of anything. Let's call it a cosmic original. Every other copy you see is a manifestation of this cosmic original.

I use these terms because I don't believe they are currently in use. So when you see the Lord Shiva over the road, is it a copy of Lord Shiva? Of course not, it is the real guy. And so it should be with all text. We should never have to type anything twice.

Transclusion: you are simulating and enacting and bringing about a situation in which all instances can be regarded as the master. Naturally there must be many copies and this is a point that many people have missed because of the emphasis on the original."

Generalized Links, Micropayment and Transcopyright

Transclusions in HTML

Transclusions are an advanced technique for the inclusion of existing content into new documents without the need to duplicate it.

Josef Kolbitsch, Hermann Maurer, Transclusions in an HTML-Based Environment

Hence, such nice concepts in Webology, like n-way linking, have absolutely nothing to do with the ‘two-way linking’ of a “double structure of abstracted literary connection -- *content links* and *transclusion* -- constitute *xanalogical structure*.” (Nelson) http://www.kolbitsch.org/research/transclusions/

1.2.2. Locatedness of documents

Again, the same at different places, without ‘physical’ representation by copy-and-paste. "Transclusions are not copies and they are not instances, but ‘the same thing knowably and visibly in more than one place’. “ (Nelson)

In contrast, “As the nodes need not have a fixed place in a spatial order to form this network of text (and other hypermedia), hypertext structure is commonly analyzed by means of graph theory.” (Kolbitsch)

1.2.3. Accessibility: Abstractness and locatedness

There is an interesting antagonism between abstractness and locatedness of documents. It could be expected that the abstractness of the text model is covered by a topological space and its graph theoretical representations where places don’t matter and documents are represented abstractly and place-free.

Hence the type of abstractness of ‘electronic’ (xanalogical) documents is of a different kind as the abstractness of a topological space. The difference might be termed as that of “connectivity of links” in contrast to the “deep connectivity” of transclusions.

"As Nelson is fond of saying, all this means is making and maintaining connections between things that are the same (Nelson 1995), or ‘deep connectivity’ as the Udanax community term it. Remote instances remain part of the same virtual object, wherever they are.” (Belinda Barnet)

This might be one of the difficulties to explain properly xanalogical concepts. Their abstractness is concretization, while ordinary abstractness of texts is ‘generalization’.

1.3. Xanadu and semiotics

A semiotic reconstruction in the framework of the purely syntactic XML wouldn’t change much, neither. Semiotics in its triadic-trichotomic form (Peirce, Bense), or even in its tetradic extension by Toth, is still framed, bracket and caged by the decision and necessity of identification and uniqueness. It seems that semiotic based approaches are missing the point.

1.3.1. Xanadu semiotics, citations

"Let us now try to use those notions for analysing the main features of Web pages. Web pages are so-called hypertexts, that is, texts with some of their components (words or sentences), possibly linked to other (hyper)texts, and so on and so forth. The reader can navigate through the whole text in a non-linear manner, by activating so-called hot links or anchor points that are linking some piece of text to some other.

"These links are an obvious example of indexes, with a word pointing to (referring to) its definition or to some related piece of information. The WWW merely extends the basic notions of hypertext by making it possible for one index to refer to some physically-distant location on a remote computer somewhere else on the Internet, together, of course, with the ability to link to and therefore communicate images and sound.

However in order to act as an index, a sign has to be recognized as such, i.e. the index has to exhibit itself as a reference. This is done in hypertext by marking the hot links in blue ink, in order to make the reader aware that he can jump to another piece of hypertext or image, therefore using a conventional symbol in order to "show" the index as such {...}

As in all semiotic systems, we have seen that the web is a mesh of icons, indexes and symbols, with each type of the trichotomy indeed depending on the others, even for its own definition.”

Philippe Codognet, THE SEMIOTICS OF THE WEB
http://pauillac.inria.fr/~codognet/web.html

"Intertextuality is a term introduced by Julia Kristeva and widely adopted by literary theorists to designate the complex ways in which a given text is related to other texts. Just as there is no sign apart from other signs, there are no texts apart from other texts. In Kristeva’s words, “every text is constructed as a mosaic of other texts, every text is an absorption and transformation of other texts.”

"Nielsen points out that “the fact that a system is multimedia-based does not make it hypertext. [...] Only when users interactively take control of a set of dynamic links among units of information does a system get to be hypertext.”

Moritz Neumüller, Hypertext Semiotics in the Commercialized Internet
http://sammelpunkt.philo.at:8080/23/2/ht_semiotics.pdf"
"Xanadu is a system for registered and owned content with thin document shells, re-usable by reference, connectable and intercomparable sideways over a vast address space (Nelson 1999, interview)."

1.3.2. Identity, copy, original
The main strategy of classical attempts to implement Xanadu concepts in the framework of HTML, XML, XPath and others is quite straightforward but in full denial of the difference of original-based identity texts and Xanadu texts, which, whatever it means, are conceived as origin-free.

"Transclusion: you are simulating and enacting and bringing about a situation in which all instances can be regarded as the master."

There are two identity concepts in the game, one, the classical, is an ontological and logical identity concept based on subject-free, i.e. user-free, existence of objects, i.e. texts. Here, there is a strict hierarchy between the original and its copy; and the plagiat-police is well equiped behind the corner. Originals are first, copies are second.

The Xanadu ‘identity’ concept is not an onto-logical but a reflectional and cognitive concept of the pragmatics of using, i.e. interaction with texts.

With that, the plagiate-police gets jobless and confused:

"Transclusions allow authors to include portions of existing documents into their own articles without duplicating them."

"Transclusions are designed as complete replacement for all cut-and-paste mechanisms in use. Nelson argues that cut-and-paste is not what people actually want to do but that it is a restriction imposed upon authors by the nature of paper." (Kolbitsch, p. 162)

The mentioned sentence is a citation, accessible to TurnItin-control. I had to copy and paste the text from CIT704.PDF to my text in progress. No transclusion accessible! It is still very difficult to grasp a textuality beyond ontological identity.

But the reasons are simple. Only, it is postulated, if texts have an identity, they can be owned by me, being my possession. Only then, I can get a degree and a patent and sell it and get rich or bankrupt.
Hence, don’t promote the real thing!

Transcopyright and micropayment
This point, textual identity and authorship beyond ontological identity, was well reflected by Nelson’s early concept of transcopyright and micropayment for/in Xanadu.

"Whenever a reader views a transclusion, a note about the rights associated with the transcluded content is added, and a micropayment is made to the corresponding owner. Nelson names this model transcopyright." (Kolbitsch, p.162)

"The on-line copyright problem may be resolvable by a simple, sweeping permission method. This proposed system, which anyone may use, allows broad re-use of materials in exchange for automatic tracking of ownership. Payment goes to the original publisher and credit to the original author (Nelson 1995)."

"Necessarily, a mechanism must be put in place to permit the system to charge for instances, a micropayment system which provides a bridge to the original from each instance. Critically, this bridge should never break; links should not be outdated. At the same time, the bridge must leave no trace of who bought the pieces, as this would make reading political. As such, Xanadu would require a micropayment system parallel to the docuverse." (Belinda Barnet)

There are educational problems too. Computer scientists and engineers are not trained in humanities, like hermeneutics, rhetorics, comparatistics, etc. and their ambiguous, complex, multi-layered texts. On the other hand, cultural scientists are not trained in computer science and programming. Hence, Ted Nelson’s project Xanadu was not only to early in time but trapped into mutual misunderstandings.

Madonna, neither original nor copy
In cultural history there are a lot of such paradox situations. Take a iconoclastic Madonna! She is the real Madonna! No copy, exclusive singularity. But from time to time she turns into a pictorial object, and has to be refreshed, repaired or exchanged with a more fancier one. During this procedure she surely didn't change her mode of existence into a copy. What had to be restored was the material, which has nothing to do with the Madonna as the real Madonna. Nothing at her body was lifted. In fact, to speak about an original includes a concept of the opposite, the copy. But the Madonna is the Madonna and the Madonna is nothing else than the Madonna in uniqueness. Albeit the neighbor church will claim, without any logical contradictions or ontological conflicts, the same for their own unique Madonna. Hence, uniqueness and multitude, 'original' and 'copies' remain, in this world-view, in harmony.

Similar figure had been at work with the Ancient Egyptian Gods.

**List of changes**

Change in identity concept, chiasm of original/copy.
From physical (linguistic) to electronic (virtual, xanalogical) text.
From information to knowledge.
From links to transclusions.
From copyright to transcopyright.
From shopping to micropayment.

---

**2. Diamonds, bi-signs and textemes**

Up to now, the classical concept of a link didn’t produce any serious scientific problems, conceptually and for implementation. Links have a simple logical structure: they are broken (dead) or not-broken (alive).

Nelson’s extension of the concept of links is radically abstracting from the physical and linguistic paradigm of documents. His ‘transclusions’ and ‘content links’ are much more abstract than syntactic links. But their logical status seems to be simple too. They are ‘unbreakable’ or, and this may become a problem, “breakable”.

Hypertextuality in the sense of the Web and its WEB-0.X-mythology, is restricted to a unidirectional exchange of signs as data between identical addresses without environments. Web links are not only uni-directional by definition but they have only two logical states: broken/unbroken.

It would be great to have a more dynamic bi-directional Web connectivity in the sense of transclusions (Ted Nelson). But Xanadu links are postulated as UNBREAKABLE. Does it matter if they are one- or two-way links if they are not qualified to perish? [http://www.xanadu.com/xuTheModel/](http://www.xanadu.com/xuTheModel/)

"Long ago we considered on-line documents. One of the first questions we asked was: "How can computers improve on paper documents?" Our principal answer: "By keeping every quotation connected to its source." We still believe this. However, those who created today's computer world didn't get that documents should be different now. They imitated paper. We see this as retrograde, like the buggy-whip sockets on the early horseless carriages." (Ted Nelson) [http://www.xanadu.com.au/transquoter/](http://www.xanadu.com.au/transquoter/)

Perishing links are neither breakable nor unbreakable, they are enabling such differences, uni- and pluri-directional. textemes with their environments and chiastic interactions are enabling links to perish, to be, as reductions, ordinary links, which might be broken/unbroken or even unbreakable.

Nevertheless, actions in textemes and between textemes are not links but interactions able of interactionality, reflectonality and interventionality. Hence, they have their life. But all that, endless self-generation of signs and contextuality of signs and texts, is well known and taught endlessly. But does it matter?

"Just as there is no sign apart from other signs, there are no texts apart from other texts. In Kristeva’s words, "every text is constructed as a mosaic of other texts, every text is an absorption and transformation of other texts."

As it was said at another place, an endless repetition of a sentence is not a truth-criteria. The truth-value of sentence might not be what is significant for interactions. True sentences without any relevance are dead.

Not only that the term “endless” and, e.g the metaphor “a mosaic of other texts” (Kristeva) is
not scientifically explained at any other semiotic considerations, its insistence runs out of relevance.

Who cares that, after, e.g Peirce and Derrida, endless iterability of signs is constitutive for sign activities. Later studies from Caputo or Gasché about infinity are badly hiding their weakness.

2.1. Limits of semiosis

How can a sign realize inter-activity, a prerequisite of any hypertextuality, if it is constitutionally depraved of any environment? In other words, the triadic-trichotomic concept of semiosis (sign production) with all its differentiations is not offering a single distinction, concept or mechanism to realize a semiotics for an interplay between different semiotic systems, i.e. trans-semiotic and inter-semiotic.

Textemes, as applications of polycontextural diamonds, are distributed over kenomic loci. Hence, the concept and mechanism of loci gives us a hint to understand textuality in a non-ontological and non-topological sense.

Disseminated semiotics gets their ontological orientation bracketed and neutralized. Classical semiotics is furthermore blind for its ontological anchoring in uniqueness. Textemes are per se anchored in different configurations of disseminated anchors. Anchors are not monolithic, they have different functionalities to anchor systems and environments, concurrently or chiastic.

Textemes are representing whole semiotic systems, i.e. semiotics. Textemes are distributed and mediated, i.e. polycontexturaly disseminated over different loci of a kenomic grid. Because there is no priviledged beginning for disseminated semiotics, there is no original semiotics as a beginning of all semiotics; all semiotics are ‘copies of copies’.

Applied to XML. If contexturally disseminated textemes (semiotics) are intra-structurally interpreted by XML, then XML gets disseminated as well; and there is no original XML left. For a classical understanding, this is utter nonsense. Classical science is conceiving this situation manorial: there is one and only one real XML (and its millions of dialects) but uncountable applications of it. XML for everything. Thus, there is, without surprise, a strict hierarchy between the original and the copy of XML.

All those sophisticated studies about semiotic interactivity, reflexionality and interventionality, in whatever field, Hypertext, Anthropology, Nursery, are permanently confusing theory and application.

Without doubt, semiotics, as well as logic, can be applied in many ways to model interaction and hypertexts, and more. This is in full harmony with Aristotle and later. But it is not harmonious with Ancient Chinese mathematics. There, ‘application’ is ‘theory’- and vice versa.

Semiotics as semiotics has no environments as semiotics. Therefore, semiotics as such has no possibility of semiotic interaction with semiotics strange, xenomorph, to semiotics.

Hence, Sowa’s statement, “The Internet is a giant semiotic system”, is not the real thing at all. Again, albeit semiotics might produce interesting insights into the character of the Web, Ontologies and Hypertext, it is fundamentally inappropriate for an understanding of the main properties of a Xanadu based Docuvers (texts, documents, semantics) with its aspects of abstractness, situatedness, polylogic and liveliness of a new Web.
2.2. The idea of textemes

As Alfred Toth, an eminent semiotician, mentioned, the introduction of diamond category theory had been opening up unforeseen possibilities for further developments of theoretical semiotics as a purely semiotic discipline. Hence, let's try to apply it!

On the base of diamond theory, I introduced, as a very first step or risk, the idea of textemes. This is conceptually straightforward because it is an interpretation of the mechanism of the composition and combination of anchored diamonds. Recall, diamonds are conceived as systems with inner and outer environments per se. Hence, different diamonds might be combined by their different but interacting external environments. Other modes of combination and interactions might be omitted for now. Anchors had been omitted in recent publications to focus on the new aspects of diamonds. Anchoring was introduced in the late 90s, following a hint from Cartwell, to concretize conceptual graphs of operations and their proemiality.

Texteme scheme, concurrent

\[
\begin{array}{c|c}
\text{bi-sign}_1 & \text{bi-sign}_2 \\
\hline
M & M \\
\downarrow & \downarrow \\
O \leftarrow I & I \rightarrow O \\
& \\
[1, 1] & [2, 2] \\
\end{array}
\]

**texteme**

diamond = (sign + environment)
bi-sign = (diamond + 2-anchor)
texteme = (composed bi-signs + chiasm).

2.3. Textemes and text theory

Classical and post-structuralistic text theory is, despite all kinds of subversion against its heritage, based on classical sémiologie and linguistics. Hence, textemes, in a post-structuralist sense, are based on the chain of

\[
\text{grapheme} \rightarrow \text{phoneme} \rightarrow \text{morpheme} \rightarrow \text{signification},
\]

with its foundation in linguistics, i.e. the theory of spoken language and its conflicting concepts of writing.

Textemes for ‘electronic’ texts, which are multimedial, virtual and distributed, are not based on a linguistic chain of logocentric abstractions and idealizations. Textemes as proposed in this paper are epistemologically not based on semiotics but on diamond theory. In some sense, textemes can be seen as based on a diamond understanding of systems and their specific environments. More precisely, textemes are based on an interplay of diamonds mediated by their external environments.

The fact, that on a micro-analytical level, links might have a pointer-structure and therefore a semiotic representation as indexes of the sign process, is secondary, and based on the structural interplay between diamonds and bi-signs.
2.4. Textemes and interactions

If we accept the limited value of sign systems for interactivity, it seems to be interesting to apply the idea, concept and formalism of textemes to study a new concept of links as *interactions*, with all their possible properties of interactionality, reflectionality and interventionality, to mention some important features.

I will not use *semiotic glue* to connect different semiotic action systems together but the post-semiotic concept of an environment of *diamonds* as supported by textemes.

The fact of the *dissemination* of textemes is subverting the systemic identity of the involved semiotics.

This change in the *ontological* status of textemes, semiotics and contextures by dissemination has to be kept in mind if the following thoughts are focusing on environments, interactions and links. Such links, environments and interactions are not thematized in the framework of cybernetic system theory or data processing of Multi-Agent Systems (MAS).

Utilizing previous constructions about reflectional interactivity in general, some diagrams from other papers might elude the mist of primary conceptualizations.

A *sign system* shall be modeled, in general, first abstracting from its semiotic properties, by its contextual subsystems $S_b$, $i \in \mathbb{N}$ at a structural (kenomic) place $O_j$, $j \in \mathbb{N}$.

Each subsystems of a sign system has its own neighbor system.

As a first step, to focus on the *environments*, the anchors shall be omitted. With a second step, the specific semiotic characterization, i.e. M, I, O, shall be replaced by a general contextual scheme.

What’s the meaning of anchors anyway?

Anchors don’t exist in semiotics. The only classical reason could be found in the “Satz vom zureichenden Grund” (Leibniz) or the “causa (forma) teleologica” (Aristotle) of ontology and epistemology. But, because there is one and only one metaphysical reason for existence and truth postulated by classical thinking, its notation simply can be omitted.

Anchors are getting more interesting if a multitude of autonomous semiotics and their environments, i.e. textemes, are accepted. Textemes might be anchored for themselves or by others. The same for environments, they might be anchored together with their semiotics or by anchors of other semiotics. This could be called the *architectonics* of anchors. But there is also dynamics involved. *Metamorphosis* between textemes might involve anchors. Hence, an anchor of one system might function as a system of another texteme.

For reasons of introduction, such complex metamorphosis of anchors shall be omitted too.

2.4.1. Elementary textemes
Formula notation for 0 – anchored 2 – textemes

(1, 2) – texteme contextual scheme

\[ \text{sign}_1 = O_1 \quad \text{sign}_2 = O_2 \]

\[ S_1 \quad S_1 \]
\[ \downarrow \quad \downarrow \]
\[ S_3 \leftarrow S_2 \quad S_4 \iff S_4 \quad S_2 \rightarrow S_3 \]

Bracket versions:

\[ \text{texteme}^{(2,1)} \]
\[ \left[ \left[ \begin{array}{c} 1, 2, 3 \end{array} \right] \right] \]
\[ \left[ \begin{array}{c} 1, 2, 3 \end{array} \right] \left[ \begin{array}{c} 1, 2, 3 \end{array} \right] \]

\[ \text{bi – sign}^{(1,1)} \]
\[ \left[ \begin{array}{c} 1, 2, 3, 4 \end{array} \right] \]
\[ \left( \begin{array}{c} 1, 1 \end{array} \right) \]
elementary texteme = \[ [[S^1, s^1][S^2, s^2]] q, (s^1 = s^2) \]

texteme(2,1) = [[[Sem^1 | env^1][Sem^2 | env^2]]: < anch >],
(env^1 α env^2)

composition of textemes

texteme(m,1) = [\[ \begin{array}{c}
Sem^1 & env^1 \\
Sem^2 & env^2 \\
\vdots \\
Sem^m & env^m
\end{array} \] ; < anch >]
(env^i α env^j), 1 ≤ i ≠ j ≤ m, m ∈ N

mediation of textemes

2.4.2. Composed textemes

\[
\left( \left( M_\alpha \rightarrow I_\omega \right) \circ \left( I_\alpha \rightarrow O_\omega \right) \right)^{(1,1)} \circ \left( \left( M_\alpha \rightarrow I_\omega \right) \circ \left( I_\alpha \rightarrow O_\omega \right) \right)^{(1,2)}
\]

\[
(M_\alpha \rightarrow O_\omega)^{(1,1)} \bigg( (\bar{\alpha} \rightarrow \bar{\alpha})^{(1)} \bigg) \bigg( (M_\alpha \rightarrow O_\omega)^{(1,2)} \bigg)
\]

Diamond composition rule for homogeneous semiotic texteme
2.4.3. Mediated textemes

4-fold semiotics

A general scheme for a 4-fold, in contrast to triadic semiotics, might first be introduced as a mediation of 4 triadic semiotics. Such a construct shall then be interpreted as a genuine 4-fold structure with, e.g. the formal distinctions of our-medium, me-interpretant, you-interpretant and our-object, all triadic distinctions modified by the whole -structure of the construction.

Only with the introduction of a semiotic complexity of at least 4, mechanism of view-points and corresponding as-abstractions as differences and chiasms between two interpretants or semiotic agents are conceptually and formally realizable. Hence, an interpretation of a text as at once being an original and a copy are conceivable without logical-ontological contradictions.
An interpretation of a 4–contextual semiotics

\[
\text{Sem}^{(4,1)} = \begin{pmatrix}
M_{1,3,4} & \rightarrow & O_{1,3}/M_2 \\
\downarrow & \times & \downarrow \\
I_{2,3,4} & \rightarrow & I_1/O_{2,4}
\end{pmatrix}
\]

with:
\[
\text{sem}_i = (M, O, I)_i, \ i = 1, 2, 3, 4
\]

and the matching conditions:

\[
\begin{align*}
M_1 &= M_3 = M_4 \\
O_1 &= O_2 = O_3 \\
I_1 &= I_2 = I_3 = I_4
\end{align*}
\]

4-fold textemes

An the base of the shortly sketched 4-fold semiotics, diamonds and textemes are naturally introduced.
2.4.4. Interactions
Interaction in this case is properly playing with the difference of inner- and outer-environments of acting systems. A two-way link is an interaction, i.e. a mutual bi-directional interaction between two autonomous systems in the mode of communication between the operations “put” and “get” in relation to the environments of both systems, and mirrored in a third communicational system.

A bi-directional link might be modeled as a bi-arrow (graph) between two nodes. Obviously, interactions are not adequately modeled by graph theoretical concepts and methods.

### 2.4.5. Links

Links in identity systems are connections between two entities. Even for physical systems it isn’t always easy to understand how bi-directional or two-way activity could happen. Conceptually, a source (domain, initial object) can’t function at once as its opposite, a target (codomain, final object). Mathematically, there is no problem involved. Links are arrows between nodes.

The saying, “there are no texts apart from other texts”, which is implying some detachments from an origin, or Nelson’s “copy of copies”, might be a post-modern move against conceptual fundamentalism but this gesture is still caged, by negation and rejection, in the logocentric understanding of negation, iteration, continuity, and origin.

"Nelson mentions that there is a fundamental difference between links and transclusions yet fails to clarify and elaborate.

• Links different - Transclusions same
• Is the memex building trails through transclusions rather than links?"

If there is no origin, then everything might function as an origin, and this is not another abstract statement but is itself involved in the formalism of chiasms of thematizations of the interplay of origins and copies as this and that.
Links in the paradigm of Xanadu, therefore, have to be understood in such an interplay of as-abstractions.

Again:

"Transclusion: you are simulating and enacting and bringing about a situation in which all instances can be regarded as the master."

"There is only one copy, one master copy of anything. Let's call it a cosmic original. Every other copy you see is a manifestation of this cosmic original."

And obviously, there is no cosmic original or Kantian Ding an sich. If it would exist, we wouldn't have been chosen to experience it..

Hence, Xanadu's text concept is "parallel documents".

"Parallel documents are everywhere, but are not generally acknowledged. There are relatively few explicitly parallel documents (like Tom Stoppard's play "Rosencrantz and Guildenstern Are Dead", which is explicitly parallel to "Hamlet" -- showing events that occur offstage in "Hamlet", and vice versa). But implicitly parallel documents are everywhere -- the parallelism of commentaries, the parallelism of long and short versions of reports, the parallelism of translations, the parallelism of holy books [Nelson 1998]. It is vital that we be able to see this parallelism of documents and to intercompare and work with their side-by-side connection."

The same lack of conceptual clarity or functionality is produced by the property "parallel documents" of Xanadu. It can be postulated that parallelism of texts needs an operative concept of environments of texts and neighbor texts which is able to explain and implement the interplay between parallel and orthogonal documents. Otherwise, such parallelism is easily reduced to linearity and hierarchy.

Methods of visualizations and implementations
"transpointing windows"
"All documents are parallel."
zigzag

2.4.6. Logic of content links (clinks)

Web

Links in identity systems are connections between two entities, realizing the two states of a binary situation: realized/not-realized or broken/unbroken.

Textemes

Complexions of textemes are realizing corresponding complexions of logical states. Such complexions of disseminated, i.e. distributed and mediated logical states are demanding a corresponding polycontextural logic to their adequate logical modeling and implementation.

Xanadu

In a world without original, each of the many simultaneous relations between texts is entitled to its own logical status of being an original and a copy.

This might be modeled by the distinction positive (pos) as original and negative (neg) as copy (mirror) of diamond logic. The following examples proposed are restricted to diamonds. It shouldn’t be a big deal to apply the results to textemes as textemes are based on an interplay of two diamonds.

Hypermedia and Unified Data Structure

Xanadu's text and document concept is multi-medial from the beginning.

Again, what does it mean and how does it work? The new paradigm is declared as “The Age of the Unified Data Structure”. But as with all unified and type-free declarations, circularity
and endless regress is programmed.

What kind of data structure is meant if everything is unified into a general data type? Another point is obvious, if the distinction original/copy collapses, all is one. This is the common, post-modern understanding of the rejection of origins with the result of nil operativity.

As developed at other places and sketched in this paper, there is another understanding too. If there is no origin, there might be many origins. That is, everything might function as an origin or as a copy. In other words, the operation of negation in “no this-and-that” is based on distinction, and if there is no distinction left then negation is not applicable. Hence, what we need is not a logic of universal everything but a logic of the mechanism of specific change. The change from origin to copy and from copy to origin in a specific situation, distributed over all kinds of media and media data. The Xanadu paradigm is not answering any of those questions. Therefore, there are at least two interpretations legitimately possible for a further understanding and modeling of xanalogical concepts.

One is what’s going on: a hidden type-free universalism best modeled by a type-free logic. The other is what I prefer to reflect on: a transparent and explicit polycontextural logic for the interactions of textemes based on diamonds and their environments.

ALL MATERIAL IS ONE

"Transclusion is a way to include, to quote parts of a document without losing its current (or any subsequent) contexts, and without it becoming a physical part of the new text (which could be a movie, hyperfiction document, you name it). In this fashion one might see all newly formulated or recorded texts, data, sounds, pictures as future 'boilerplate paragraphs' or fragments, available for viewing, digesting, and transclusion in new works." (Ian Feldman)

"All the contents on all of the Xanadu storage servers act as a single pool. You can send for any part of any document or link to or quote any part of any document."

http://www.aus.xanadu.com/xanadu/future.html

"5 Every document can consist of any number of parts each of which may be of any data type.
6 Every document can contain links of any type including virtual copies ("transclusions") to any other document in the system accessible to its owner.
7 Links are visible and can be followed from all endpoints."

"Transliterary structure is meant to be the fullest generalization of documents. This means being able to represent all possible document structures, and to deal with the vicissitudes of change, versioning and copyright.

Transliterary structure is the latest version of the Xanadu project.

"Documents" are packages of content constructed by authors from new and old text, audio and video, in any arrangement and pieces and desired appearance."

http://xanadu.com/XanaduSpace/bf.htm

2.4.7. Negations for logical diamonds

Logified diamond(3)
Logified elementary diamond

\[ D^{(\ell)} = \begin{bmatrix} \text{id}_4 \\ \text{id}_1 \ \text{id}_2 \\ \text{id}_3 \end{bmatrix} = \begin{bmatrix} \text{neg}_4 & \text{prop} \\ \text{pos}_1 & \text{neg}_1 \\ \text{pos}_2 & \text{neg}_2 \\ \text{pos}_3 & \text{neg}_3 \end{bmatrix} \]

Negation \( \text{non}_1 \)

\[ \text{non}_1 \left( D^{(3)} \right) = \begin{bmatrix} \text{id}_4 \\ \text{non}_1 \ \text{id}_2 \\ \text{id}_3 \end{bmatrix} \]

\[ = \begin{bmatrix} \text{neg}_4 - \text{neg}_1 & \text{pos}_1 \\ \text{up} & \text{up} \\ \text{pos}_2 - \text{pos}_3 & \text{neg}_2 \end{bmatrix} \]

Negation \( \text{non}_2 \)

\[ \text{non}_2 \left( D^{(3)} \right) = \begin{bmatrix} \text{id}_4 \\ \text{id}_1 \ \text{non}_2 \\ \text{id}_3 \end{bmatrix} \]

\[ = \begin{bmatrix} \text{pos}_1 \rightarrow \text{neg}_3 \\ \text{neg}_2 \leftarrow \text{pos}_2 - \text{pos}_4 \end{bmatrix} \]

System notation for negations \( \text{non}_i \), \( i = 1, 2, 3, 4 \)

\[ \begin{bmatrix} \text{id}_4 \\ \text{non} \ \text{id}_1 \\ \text{perm}_1 \end{bmatrix} \]

\[ \begin{bmatrix} \text{sgn}_4 \\ \text{perm}_1 \end{bmatrix} \]
\[ \neg_1 \left( \neg_2 \left( \neg_1 \left( D^{(3)} \right) \right) \right) = \neg_2 \left( \neg_1 \left( \neg_2 \left( D^{(3)} \right) \right) \right) \]

\[ \neg_1 \left( \neg_2 \left( \neg_1 \left( D^{(3)} \right) \right) \right) = \begin{bmatrix} S_4 \\ S_1 \\ S_5 \end{bmatrix} \xrightarrow{\text{perm}_1} \begin{bmatrix} S_4 \\ S_1 \\ S_5 \end{bmatrix} \xrightarrow{\text{perm}_2} \begin{bmatrix} S_4 \\ S_3 \\ S_2 \end{bmatrix} \xrightarrow{\text{perm}_1} \begin{bmatrix} S_4 \\ S_3 \\ S_2 \end{bmatrix}. \]

\[ \neg_2 \left( \neg_1 \left( \neg_2 \left( D^{(3)} \right) \right) \right) = \begin{bmatrix} S_4 \\ S_1 \\ S_5 \end{bmatrix} \xrightarrow{\text{perm}_2} \begin{bmatrix} S_4 \\ S_3 \\ S_2 \end{bmatrix} \xrightarrow{\text{perm}_1} \begin{bmatrix} S_4 \\ S_3 \\ S_2 \end{bmatrix} \xrightarrow{\text{perm}_2} \begin{bmatrix} S_4 \\ S_3 \\ S_2 \end{bmatrix}. \]

Logified diamond$^{(4)}$
2.4.8. Transclusions and transjunctions

What is a transclusion logically? Is there any similarity, on a logical level, between transclusions and transjunctions?

"A transclusion is the reuse in whole or in part of another node in one node's rendering. That is, one node including another node when it is being displayed. A transclusion is different from pure copying, however, in that only a reference to the foreign material is stored."

http://www.usemod.com/cgi-bin/mb.pl?TransClusion

Transclusions are including data from other places without copying and duplicating the data.
Logical transjunctions are mirroring logical data from logical functions of other places into their own logical domain. That is, transjunctions are including logical values of other logical systems, without copying them into their domain. Transjunctions are polylogical functions representing interactions between different logical systems. Such representations and inclusions are not set theoretical operations.

The example shows an interaction in a 3-contextural logic between Logic\(_1\) and Logic\(_2\), Logic\(_3\). Logic\(_1\) is including parts of Logic\(_2\) and Logic\(_3\).
2.4.9. Transjunctions in textemes

Transjunction are naturally modeled in semiotics and textemes following the strategy.
sketched above. The conditions for transjunctions and transclusions in general are
distributed and mediated systems, like logics, semiotics, diamonds and textemes. Textemes
are taking place, occupying a structural locus, this enables interactions, transclusions and
transjunctions, between autonomous systems.

<table>
<thead>
<tr>
<th>transjunction in Semiotics$^{(3)}$</th>

<td>M1</td>
</tr>
<tr>
<td>M2</td>
</tr>
<tr>
<td>M3</td>
</tr>
</tbody>
</table>

2.5. Structure of environments for transclusions in textemes

The structural possibilities of environments are now offering different realizations of interactions,
concretized as links, transclusions and other interactions.

Depending on the complexity of interplaying textemes, different structural possibilities for interaction for
interactionality, reflectionality to interventionality are accessible for implementation.

Depending on the structure of the common environments, actions like reflection, interaction and intervention
are available and supported for interplaying textemes.

**Reflection**: Bidirectional environments are offering minimal requisites for mutual reflection.
**Interaction**: Mutual autonomy of different environments are enabling interaction.
**Intervention**: Different antidromic environments offer the possibility of intervention between the different
environmental systems.

The bilateral interaction between the two isomorphic environments is a new topic added to the unilateral
environment of diamonds.

\[
\begin{array}{c}
\begin{array}{c}
\omega \leftrightarrow \gamma
\end{array}
\end{array}
\]

In this case (1), both actors are agreeing to accept a common environment.

\[
\begin{array}{c}
\begin{array}{c}
\omega \leftrightarrow \gamma
\end{array}
\end{array}
\]

In this case (2), both actors agree in the autonomy and simultaneity of their environments,
which are accepted as their common environment.

\[
\begin{array}{c}
\begin{array}{c}
\omega \leftrightarrow \gamma
\end{array}
\end{array}
\]

In this case (3), two different environments are accepted as the common environment. A
further task would be to analyze their intra-environmental structure of cooperation.

\[
\begin{array}{c}
\begin{array}{c}
\omega \leftrightarrow \gamma
\end{array}
\end{array}
\]

In this case (4), two different, antidromic autonomous environments are accepted as the
common environment of the texteme.
In this case (5), two different and antidromic environments are accepted as the common environment of the texteme and *interventional* activities between both environments are possible.

\[
\begin{array}{|c|c|}
\hline
\tilde{l}\omega & \tilde{l}\alpha \\
\hline
\tilde{M}_\omega & \tilde{M}_\alpha \\
\hline
\end{array}
\]

In this cases (6), new combinations of textemes are required to realize parallel and orthogonal interactions. Further combinations might be introduced as applications of different patterns.
Category of Glue, Part II

Is there any glue to stop the decline of Western culture?

Rudolf Kaehr Dr.@
ThinkArt Lab Glasgow

Abstract

Part I:
A typology of different categories of glue (ordinary, super-, para-, proto-, trans-glue) are glued together with different strategies of gluing (set and category theory, combining logics, bi-category with (co)spans, polycontexturality and diamond theory). Interpretations of “interactional glue”, “nerve glue”, “logical glue” are sketched. Keywords of the dissemination of the concept of “glue” in history (Hegel, Marx, Lenin, Gunther, Derrida, Obama) and strategies (Glue, Opium, Mediation) of gluing them together under a general parapluie (ontology, society, solidarity, fear) are critically sketched.
The economical question is: Can we still afford to glue interactions together?
The category of glue isn’t blue, Categories are clueless to interaction and are banking unsecured resources.

Part II:
How to get rid of glue? From gluing to jumping. A new abstraction, the as-abstraction, and a subversion, the morpho-abstraction, has to be risked to avoid the complicity of category theory with the unavoidable exploitation of (conceptual) resources by the Western approach to interaction and communication in computer science.
To overcome the limitations of the category “glue”, contextualization and mediation in a chiastic and diamond framework has to be elaborated and achieved to create chances to surpass and subvert such cultural and technological limitations.

1. Diamond theory of interactivity

1.1. Buffering super glue
1.1.1. Gluing information

![Diagram of message-passing routines with buffering super glue.](image)
"Whatever its nature (radio waves, wires, laser beams), the carrier is called a transmission line or wave. At the other end of this line the message is decoded and transcribed into information that has meaning for the person to whom it is addressed. But in order for the recipient to recognize and use the information, there must already have been information memorized that can be compared with the message just received. A final and important point is that disturbances occurring in the transmission line (the "noise") can alter the message and change its meaning."
(Joël de Rosnay, THE MACROSCOPE, A NEW WORLD SCIENTIFIC SYSTEM)

1.1.2. Circularity of buffering information

There is obviously a kind of a well known circularity involved with the buffer paradigm. A sender is sending a message to a receiver, but this procedure is not working directly from sender to receiver, but indirectly via a buffer. Hence, the buffer is a receiver too, albeit a semi-receiver, but in its functionality to act as a buffer it has to receive the message which has to be buffered. Therefore, the buffer to work as a receiver needs a buffer, his own semi-buffer, which is enabling the main buffer to buffer the massage for a receiver. Again, this is only the beginning of an infinite regress. Our semi-buffer needs a semi-semi-buffer to semi-buffer the buffer to buffer the message for a receiver. And so on!

In other words: Super Glue isn't enough. What is needed is the ultimate super glue, the super glue of the super glue.

Some Hello!

"Those links may make you pull your hair out! The "Glue" article is all over the place, but, I think, working around the problem you're addressing." (John Powers)

The style of this “Glue”-text might succeed to reflect, “all over the place” (John Powers), the lack of strict and save interconnections between its heterogeneous parts. Also, as much is still glued together by the metaphor “glue”, the lack of continuity, deductive or explicative, is marking the gaps and the chances or challenges to choreograph jumps and salti to “bridge” together that what doesn’t belong together. What belongs together, and might be glued for ever, like mankind, nation, family, identity, doesn’t need to be bridged. It remains well placed and accessible in the labyrinth of the human cage.

especially:

1.2. Streching super glue
1.2.1. Horizontally: Meta-pattern

"For instance, a configuration in which the messages from a sender component are sent (to a receiver) through a bounded buffer defines the following diagram:"
The node labelled *cable* is the representation of the set of bindings." (Cat, p. 146)

http://www.cs.le.ac.uk/people/jfiadeiro/

1.2.2. Pfalzgraf’s Fibered Glue

Another strategy of stretching and distributing glue is given by the general techniques of fibering and indexing categories. Where is the glue of fibered distribution, e.g. of agents in Multi-Agent Systems (MAS)?

Despite a great clarification of meta-glued fusions and confusions, meta-glue is still at work and necessary to enable interaction between distributed agents in the fibered polycontextural model of MAS. Fibered distribution is modeled in the framework of *bundle* categories along a general *index* fiber, i.e. a “base manifold” (Pfalzgraf). The index fiber is gluing all those distributed free fibers together. Hence, fibered distribution is based on glue. This glue is gluing together all the fibers of stretched glue-fibres. The proposed techniques are highly sophisticated: the super glue is meta-gluing itself infinitely. That is, the base manifold or index set might be fibered itself. The construction is “recursive, fractal and self-referential” (Pfalzgraf), hence bottom-less.

“Actually, when listening to the experts speaking about polycontextural logics, he was reminded of the concept of *fiber spaces*.

This led him to the idea of introducing “logical fiberings”, i.e. taking the abstract concept of fiber bundles and combine it with logical spaces as fibers all put together over a *base manifold* (which acts as *index set* with a particular structure). Thus over each point of the base space there sits (‘resides’) a fiber which can be interpreted as the local state space of that point (‘agent’).

The fiberings method is found to be very useful in modeling communication and interaction between cooperating agents, due to the possibility to switch between a local/global point of view which is inherent to this framework.”
A more generalized approach to fibred logics is given recently by Pfalzgraf/Soboll as a “base diagram”, which is introduced with: “Fundamental important for our work is the observation that the general communication and cooperation structure of a MAS can be represented by a corresponding arrow diagram, called base diagram of the MAS.”

“To each MAS we associate such a base diagram, which represents the complete relational structure (i.e. communication in the general sense). The nodes of this arrow diagram represent agents, the arrows (and paths of arrows) hold the communication and cooperation information. This gives a category by its own right, more precisely a typed category.

In a MAS communication and cooperation (in general relations) between agents can change. This fact gives rise to the definition of the category MAS of all MAS where the objects are base diagrams of Multiagent Systems and the morphisms are MAS morphisms i.e. structure preserving maps between base diagrams.

Based on this category MAS a transformation system for Multiagent Systems can be established by applying the double pushout approach to Multiagent Systems.

"...we introduced an alternative algorithm."

[cf. DPO: Double Push Out!]

Thomas Soboll, On the Construction of Transformation Steps in the Category of Multiagent Systems

http://www.portal.acm.org/citation.cfm?id=1428606

"The scenarios of cooperating robot agents were originally devised to demonstrate how the concept of a Logical Fibering can be used in a natural way to assign a system of Distributed Logics to a MAS, where every agent has an individual local state space (fiber), the collection of all the fibers forms the global state space (fiber bundle) of the MAS.

This Fiber Bundle aspect can naturally be extended and generalized to introduce fibers of various structure types, modeling corresponding state space properties which are of relevance to model the complete state space of an agent, consisting of various modules (fibers) defining the complete type of an agent." (Pfalzgraf, p.34)

1.2.3. What are the aims of glued interactions?

Service-oriented approach
"Services add a social layer of abstraction over a component infrastructure in sense that they structure the process of interconnection (programmed interconnections).
- Services should be published at a level of abstraction that corresponds to a real-world activity or recognisable business function (which is where social complexity can be understood)
- Systems should be socially-reflective."
(Fiadeiro, 2008, p. 4)

Semantics of Service Discovery and Binding,

"For every activity a, a homomorphism B(a) of graphs between the body of B(a) and SF. (This homomorphism makes configurations reflective.)" (ibd., p.9)

"Therefore, we decided to look for algebraic mechanisms of interconnection that can capture peer-to-peer interactions among autonomous components. That is why, in this paper, we report on the use of co-spans - pairs $<f_A, f_B>$ where $f_A: A \to S$ and $f_B: B \to S$ are morphisms of a category D." (Fiadeiro, CALCO'07, p. 195)

Glue is gravitational, it holds things together by forcing them down.

1.3. Inhaling glue

Along the symbolic interaction metaphor of “I” and “Me” of a “Self”, a duplication of an agent into itself and his inner-environment might open up the possibility for a reflective modeling. Such a
reflectional distinction is reasonable only for a society of agents and is of no relevancy for a solipsistic concept of agents. The inhaling concept of reflectional glue is highly solipsistic and is celebrating gluish hedonism. Therefore, to stretch further the anthropomorphic metaphor of “I” and “Me” of a “Self” for societal interaction, a new distinction has to be sketched: the distinction between the homogeneity of (empirically) different “Selfs’s” and a heterogeneity between such “Selfs” and “Thou”. This move is quickly over-stretching ordinary glue. Between Herbert Mead’s Self as I and Me, and Gotthard Gunther’s Thou as a fundamentally different “I” and “Me”, a chiasm demands challenging flexibility to any glue:

\[
\text{Chiasm } \left( \left( I, Me \right) \text{ self} \right| \left( I, Me \right) \text{ thou} \right).
\]

Such over-stretching is avoided by the denial of a dialogical difference between Self (or I) and Thou.

That is, the functionality of a buffer for sender and receiver could be incorporated from the outer-environment (channel) into the inner-environment of an agent as a reflectional part of the sender and receiver interaction. The inner-environment of an agent (Me) is taking the agent-specific elements of glue into its domain. Glue gets inhaled and with this incorporation it is loosing its procrastinating function as a non-computing coordinative buffer. Inhaled glue becomes part of the agent and its computational facilities.

This approach to reflectionality is leading strictly into meta-circular iterations and regresses. Quickly, the incorporated glue is starting to glue itself by incorporating its incorporated glue, endlessly.

A monocontextural modeling is drawing a strict distinction between the three identical, i.e. non-reflectional entities: Sender, Buffer, Receiver with the activities: send, receive, put, get. That is, send-->put, receive<--get. Therefore, there is no flexibility accessible to model reflectional incorporation of the functionality of buffers into the instances “sender” and “receiver”.

A polycontextural modeling is drawing a distinction between two positions and their chiastic functionality as Sender and as Receiver. Hence, distinctions like “buffer as receiver” and “receiver as buffer” and also “buffer as sender” and “sender as buffer” are accessible.

Such a movement towards an internalization of the functionality of buffers is reducing the costs of interactions. Because of its chiastic structure, such an internalization is also free of bad circularity, like the infinite regress of buffering buffers. Hence, the simple distinction between active and passive processuality of an agent (computation) and buffer (coordination) has to be transformed into an active/passive activity of agents.

2. Getting rid of glue

2.1. Interfaces

2.1.1. Interfaces as mutual representation

Glue-free mediation is still challenging the clue-less approaches of scientific modeling, formalization and implementation of interactivity and interactionality.

As sketched before, interactions mediated by buffers and their glue are interacting in the ontological-semiotic mode of is-abstractions (is-a, has-a) accepting basic presuppositions of identity-driven conceptualization and implementation, i.e. ontology, semiotics and logic.

One of the main problems of modeling in the mode of the is-abstraction is the well known polysemy of semantics and its multiple inherence. Despite the amount of academic solutions, the problem remains as long as its identity presupposition, i.e. disambiguation, isn’t changed.

The sold solutions are based on direct or indirect ad-hoc principles and one-step-thinking.
The example below is based on the ingeneous procedure "rename" (Hendle). After renaming the term, the general ontology might be prolonged from the general ontology [Thing, Person] with its university-ontology to the furniture-ontology. With this procedure, no conflict will arise. At least as long as nobody starts thinking one step further.

Cost of disambiguation and buffering
Communication of disambiguated data is cost-free. But it is naive to think that it comes without costs. In contrary, the costs of disambiguation, necessary before any procedures can happen, are enormous. But disambiguation is arbitrarily stopped and is depending on a context. With a change of context, disambiguation has to start again.

Renaming is itself a kind of a buffering, i.e. gluing procedure, lacking any interactivity:

Some renamed and extended ontologies
Extensions by renaming are ad-hoc and have to be repeated endlessly through the semantic universe, which is not restricted to the English language only. Even to stop its regress in concrete computing scenarios isn't cost-free. Fixed solutions, glued by chance, have to be re-fixed after the slightest context-change of the fixture. For complex, flexible and mobile computing, simply a disaster.

It is typical for the design of ontologies for semantic purposes in computation, like the Semantic
Web, that the medium of its thematization, i.e. language, sign systems, is not mirrored in the General Ontology Language (GOL). GOL is designed in the framework of set theory which is mirroring Aristotelian ontology. There is no place for reflection, self-reflection and interaction between autonomous subjects left.

Reflectional approaches are much involved with the, at least, triadic-trichotomic semiotic in the sense of Peirce (Goguen).

Therefore, to the whatever Aristotelian ontology, at least the “ontology” of the vocabulary “Sign” has to be added for a conservative extension of the GOL. Hence, events or phenomena are occurring as Person, Object or Sign in an (semiotically) extended ontology.

<table>
<thead>
<tr>
<th>Events</th>
<th>↓</th>
<th>↓</th>
<th>↓</th>
<th>asa</th>
</tr>
</thead>
<tbody>
<tr>
<td>Person</td>
<td>Object</td>
<td>Sign</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Again:

“No self-reference is possible unless a system acquires a certain degree of freedom. But any system is only free insofar as it is capable of interpreting its environment and choose for the regulation of its own behavior between different interpretations.” Gunther, 1968, p. 44

Hence, glued, i.e. buffered, interaction is unnecessarily cost-intensive even before any computation and coordination can happen.

There are conceptual costs, too. The identity approach, even in a 2-categorical setting, is conceptually restricting possibilities.

### 2.1.2. Polycontextural approach

A reflectional analysis of polysemy is an analysis of the semiotic actions of agents which are leading to the phenomenon of polysemy and its possible conflicts with other semiotic or logical principles. Therefore, such an analysis is more complex, because it has to describe the situation intrinsically, that is from the inside and not from the position of an external observer.

The aim of a polycontextural modeling of polysemy is to design the construction of polysemy in a finite and concrete manner.

The distinction of two fundamentally different kinds of abstractions, the is-abstraction (identification) and the as-abstraction (thematization), might help to model the reflectional situation. The formula of the as-abstraction “asa” is: “X as Y is Z”, hence, the is-abstraction “isa”, X is X, can be read as an abbreviation of: “X as X is X”.

The as-abstraction is introducing highest flexibility for modeling, designing and implementing complex reflectional situations. The as-abstraction is abstracting from the main principle of any computation and computing: the principle of identity.

<table>
<thead>
<tr>
<th>O₁</th>
<th>O₂</th>
<th>O₃</th>
</tr>
</thead>
<tbody>
<tr>
<td>S₁</td>
<td>S₂</td>
<td>S₃</td>
</tr>
<tr>
<td>S₁</td>
<td>S₂</td>
<td>S₃</td>
</tr>
<tr>
<td>S₁</td>
<td>S₂</td>
<td>S₃</td>
</tr>
</tbody>
</table>

Here, type 123
Mono-contextural "isa":
S1: Chair is part of a furniture ontology (Object),
S2: Chair is part of a department ontology (Person),
S3: Chair is part of a vocabulary ontology (Vocabulary).

Poly-contextural "isa as":
O1S1: Chair as such, that is, as an object (furniture) "Chair", Chair_{obj}.
O2S2: Chair as such, that is, as a person (head) "Chair", Chair_{pers}.
O3S3: Chair as such, that is, as the token (vocabulary) "Chair", Chair_{token}.

Here, "as such" means, that the ontologies Object, Person and Vocabulary can be studied and developed for their own, independent of their interactivity to one another but placed and mediated in the constellation of their poly-contexturality, that is, their distribution over the 3 loci, O_1, O_2 and O_3.

Voc O3S3 in Furn O1S3:
The token "Chair" as used to denote the object "Chair", Chair_{token, obj}.

Voc O3S3 in Dept O2S3:
The token "Chair" as used to denote the person "Chair", Chair_{token, Head}.

Chair O2S2 in Dept O1S2:
The object Chair as used in the person ontology Dept, Chair_{obj, Dept}.

Chair O1S1 in Furn O2S1:
The person Chair as used in the object ontology Furn, Chair_{pers, Furn}.

Reflectional situations
Chair O2S2 in Dept O1S2:
System O1S1 has in its own domain space for a mirroring of O2S2. This space for placing the mirroring of O2S2 is the reflectional capacity realized by the architectonic differentiation of system O1. In other words, O1 is able to realize the distinction between its own data and the data received by an interacting agent. Data are therefore differentiated by their source, e.g. their functionality, and not only by their content.
Chair O1S1, in Furn O2S1:
System O2S1 has in its own domain space for a mirroring of O1S1.

A (re)solution of the problem
The department Dept for itself has no conflict with polysemy. This conflict between Dept and Furn is mediated by the Voc. That is, the Person of the Dept as Chair is a person and nothing else.
The furniture Furn for itself has no conflict with polysemy. This conflict between Furn and Dept is mediated by the Voc. That is, the Chairs as objects of the Furn are chairs and nothing else.
The vocabulary Voc for itself, containing “Chair”, has no conflict with the polysemy between Dept “Chair” and Furn “Chair”.

The meaning of the polysemic situation is realised by
Meaning of (O3S3) = interaction of (O1S3, O2S3)

The conditions for a conflict arises exactly between
O1 (S1,2,3) and O2 (S1,2,3) mediated by O3S3 as visualized by the blue triangles.

Both Furn and Dept are using Voc and both are using the string Chair of Voc. Both are different and are mapping the Voc differently relative to their position, thus the Voc has to be distributed over different places according to its use or functionality. The Voc used by Furn is in another functionality than the Voc used by Dept.

Up to now we have not yet produced a contradiction but only a description of the situation of polysemy, that is, the necessary conditions for a possible ontological, semantic and logical contradiction.

A user-oriented approach to the modelling of polysemy has to ask “For whom is there a conflict?” Therefore, we have additionally to the semantic and syntactic modelling of the situation to introduce some pragmatic instances. In our example this could be the user of a Query which is answering in a contradictory manner.

Query’s contradictory answer
Now we have to deal with the contexts: (Query, Voc, Furn, Dept).
In the classic situation, the Query answers with a logical conjunction of Chair as Person and Chair as a Department member, which both are logico-semantically excluding each other and therefore producing for the user of the Query a conflicting or contradictory answer if put into a single logical conjunction.
Logic comes into the play also for the polycontextural modelling, but here conjunctions too, are distributed over different contextures. And therefore, a contradiction occurs only if we map the complex situation all together onto a single contexture.

\[(O_4 M_4) = \text{Query}\]

\text{Logic:}

Person \(\bigcap\) Object \(\bigcap\) Vocabulary = \(\emptyset\),

Person \(\text{Chair} = \neg\text{Furniture}\) \(\text{Chair} = \neg\text{Vocabulary}\) \(\text{Chair}\)

\text{Chair} \in \text{Department} \implies (\text{Chair} \neq \text{Furniture} \land \text{Chair} \neq \text{Vocabulary})

\text{Contradictory Answer:}

\((\text{Chair} \in \text{Department} \land \text{Chair} \in \text{Furniture}) \implies (\text{Chair} \in \text{Department} \land \text{Chair} \notin \text{Department})\)

\text{Polylogic}

\text{Chair} \in (\text{Department, Furniture, Vocabulary})

Person \(\bigcap\) Department = \(\emptyset\), Person = \(\neg\text{Department}\)

\[\begin{align*}
\text{Chair} \in \text{Department} \land \text{Chair} \notin \text{Furniture} \land \text{Chair} \neq \text{Vocabulary} \\
\text{Chair} = \text{Furniture} \land \text{Chair} \notin \text{Department} \land \text{Chair} \neq \text{Vocabulary} \\
\text{Chair} \in \text{Vocabulary} \land \text{Chair} \notin \text{Department} \land \text{Chair} \neq \text{Furniture}
\end{align*}\]

\text{Polylogic with Conjunctions:} \(\land^{(3)} = (\land^1 \land^2 \land^3)\).

\text{Negations:} \(\neg^i, i = 1, 2, 3\) and non-entails: \(\neg^i \in \neq^i\)

\((\text{Chair} \in \text{Department} \land \text{Chair} \notin \text{Department}) \implies (\text{Chair} \in \text{Department} \land \text{Chair} \notin \text{Department})\)

\[\begin{align*}
\text{Chair} \in \text{Department} \land \text{Chair} \notin \text{Department} \implies \emptyset \\
\text{Chair} \in \text{Furniture} \land \text{Chair} \notin \text{Department} \implies \emptyset \\
\text{Chair} \in \text{Vocabulary} \land \text{Chair} \notin \text{Department} \implies \emptyset
\end{align*}\]

\((\text{Chair} \in \text{Department} \land \text{Chair} \notin \text{Department}) \implies (\text{Chair} \in \text{Department} \land \text{Chair} \notin \text{Department})\)

\[\begin{align*}
\text{Chair} \in \text{Department} \land \text{Chair} \notin \text{Department} = \emptyset \\
\text{Chair} \in \text{Furniture} \land \text{Chair} \notin \text{Department} = \emptyset \\
\text{Chair} \in \text{Vocabulary} \land \text{Chair} \notin \text{Department} = \emptyset
\end{align*}\]

\text{Short:}

\((\text{Chair} \in \text{Department} \land \text{Chair} \notin \text{Furniture} \land \text{Chair} \neq \text{Vocabulary})\)

If we give up all the introduced ontological distinctions of polycontexturality and reducing therefore our ontologies to a single mono-contextural general ontology we saved our famous contradiction again. But now, this contradiction is a product of a well established mechanism of reduction. And sometimes it isn't wrong to have it at our disposition.

The costs of the polycontextural approach lies in its novelty and its intrinsic complexity.

Observations about observations in another worldmodel.
"Unlike observation of the first order, which sees all elements in the world as connected in one context with geometric symmetry, observation of the second order views a world that is poly-contextual (polykontextural). In the poly-contextual world, the values of social institutions may not all be in the same context. From such perspective, labeling two values in different contexts as a set of binary for comparison in the same matrix is deemed to generate inaccurate analysis. This is why "many-valued-logic" (mehrwertige Logik) is so essential in the poly-contextual world. When the values in seemingly antithetical binaries are, in fact, of different contexts, for those values to be antithetical yet mutually complementary is no longer impossible. In fact, this antithetical yet complementary pattern that is unthinkable in the realm of the world of the observation of the first order is totally consistent with the many-valued-logic of poly-contextual settings. According to Lin, this many-valued-logic is exactly the essence of traditional Chinese law and its legal system."

Review: Duan Lin. _Weibo Lun Zhongguo Chuantong Falu_ (Weber's Analysis on Chinese Traditional Law: Critiques on Weber's Comparative Sociology)
Dr. Lin Duan has provided a profound study on the demerits of Weber’s methodology. See Lin Duan, Rujia lunli yu falü wenhua: shehuixue guandian de tansuo (Confucian Ethics and Legal Culture: Exploration from Sociology), Beijing: Zhongguo zhengfa daxue, 2002, p. 93; 122.

2.2. Diamond modeling

2.2.1. General strategies
Diamond constructions are reducing the costs of interactivity by the fact that their operations are intrinsically interactive. That is, the interplay of the conditions of matching and the compositions themselves are reflected in the complementarity of categories and saltatories of diamonds. Diamonds are offering more structural space to model and implement interactivity than categories and n-categories.

The general strategy to reduce the costs of interaction is to find a concept and apparatus that is offering a wider logical scope to model the dynamics of the differences between actors and their communication. The other part of the strategy is to separate basic functions, like coordination/computation (Fiadeiro) or locality/connectivity (Milner). Both strategies are changing the priority of time in computing to the favor of space, “metaphorical space” (Milner) for the localization of separated aspects of (mobile) computation.

This enlargement of “metaphorical space” happens for computer science in different steps, all trying to capitalize on new and broader concepts from other disciplines or on developing own computer science specific concepts, like, e.g. Goguen’s Institutions and Padawitz’ Swinging Types.

Modal logics
Coalgebra
Category theory
Combining logics
n-Category theory

But there are some fundamental limitations occurring in this endeavour.

"Grammatologically, the Western notational system is not offering space in itself to place sameness and otherness necessary to realize interaction/ality. Alphabetism is not prepared to challenge the dynamics of interaction directly. The Chinese writing system in its scriptural structuration, is able to place complex differences into itself, necessary for the development and design of formal systems and programming languages of interaction. The challenge of interactionality to Western thinking, modeling and design interactivity has to be confronted with the decline of the scientific power of alpha-numeric notational systems as media of living in a complex world. “ (Interactivity, 2008)

To overcome such limitations, the graphematic and trans-classical strategies of:
Polycontexturality,
Morpho- and Kenogrammatics,
Proemiality and Chiasm,
Diamond theory,

had been introduced as subversive and experimental interventions and realized in form of fragmentarism.
It seems that for each step there is a progressive extension of the possibilities of ‘space-ing’ interactionality and reflectionality of notational systems.

All known strategies have their own advantages and deficits. The main problems are not so much the limitations of the specific approaches but their applications to domains for which they are not specifically designed and are therefore inadequate albeit the compagning propaganda.

It surely would be an absurd misunderstanding, also quite typical for the ‘quick-reading’ ritual of censors, to believe that I am hallucinating a computer science based on Ancient Chinese hieroglyphs. (Kaehr, The Chinese Challenge).

2.2.2. Categorical composition

“Category Theory is advocated as a good mathematical structure for this integration precisely because it focuses on relationships and interactions! The focus that Category Theory puts on morphisms, as structure preserving mappings, is paramount for Software Architectures because it is the morphisms that determine the nature of the interconnections that can be established between objects (system components).” (Fiadeiro, 2002, p. 12)

Category oriented implementations are based on the concept of categorical composition of morphisms which in itself is neither interactive nor reflective. It is mentioned that morphisms are representing interactions and interconnections. This might be appropriate for non-reflectional interactions, like actions on objects (Bunge). Reflection, and especially social reflection, gets into conceptual trouble. Interaction might be represented by morphisms, but reflection would then be represented by ‘morphisms of morphisms’.

This figure leads automatically to the question: Is a morphism of a morphism, i.e. a second-order morphism (cf. Fiadeiro’s homomorphism!) conceptually a morphism or something else? If it is conceived as a morphism, we are back again to the first-order concept of morphisms, i.e. to morphisms without reflection. And hence, the second-order concept can be reduced to a first-order concept. Otherwise, if the construct of a morphism of a morphism isn’t reducible to a first-order categorical concept, then it is violating the axioms of the framework of category theory, especially its axiom of identity.

Hence, the workspace of the categorical interpretation of interactivity is modeled by the metaphors of super glue, for categories, and of stretched glue, for n-categories.

Such societal and reflectional metaphors are reasonable for computer science only if they are explicitly declared as weak metaphors, not suitable for social and psychological adaption. Albeit the fact that interdisciplinary confusions are supporting academic marketing strategies, they are nevertheless boring and economically and politically dangerous.

2.2.3. Dissemination

The dissemination of categorical systems in the sense of polycontexturality is offering the possibility of interactionality and reflectionality. But still for a considerable price of interpretative, i.e. observer depending, delays. Interactivity between disseminated contextual systems is guided by the strategies and mechanism of proemiality and are realized as chiasm.

Each contexture of a contextual compound constellation is composed by sub-contextures, usually as elementary morphisms and is of trichotomic structure. Thus, polycontexturality is a dissemination of trichotomic structures, that are, in themselves, not prepared to reflect their interactionality. Interactionality and reflectionality are introduced polycontexturally as interactions between different contextures, i.e. as trans-contextural events.

2.2.4. Chiasm

From an observer theoretical point of view, chiasms between contextures, realizing interactivity, is observed from an external observer. Hence, their internal mechanism is still not yet glue-free, but involved in a kind of a dissolution of the adhesion of glue, i.e. the chiastic jump between disseminated contextures is still sniffing glue and sticking the elements of mediation together by some metaphysical or kenomic glue.

Chiastic glue is technically delivered mainly by the coincidence relations of chiasms. They are responsible for guaranteeing that the distributed order relations, which are themselves glued by definition (matching conditions), and their risky exchange relations interact in harmony with similitude. The fulfillment of the coincidence relations in a chiasm is establishing categorial
similarity, i.e. family resemblance of categorial kind. Otherwise, chiastic glue would be over-stretched and losing its ends.

In other words, for chiasms to work, their relationality has to be in categorial harmony of similitude. Chiastic concepts have to fit together by general mappings or morphisms. Chiastic jumps, possible in chiasms, are insured by harmony and traced back and ruled by the coincidence or similarity relations. This important restriction and complicity to similarity is necessary for chiasms to avoid empty statements, like “everything is connected”, of universal connectionism. It also prevents jumps into the void.

Super-glue and stretched super-glue interactions, realized as buffers and buffered systems, don’t need observers. They are designed and conceived as observer-independent objective utilities and mechanisms. Therefore, the observer-independent approaches might be adequate for signal and information processing (information interaction) but are missing the demands for interactional situations of semantic and knowledge modeling and computation (symbolic interaction).

2.2.5. Diamondization

Jumps without guaranteed security have to be realized by somersaults, i.e. by salti. Salti are in a strict discontexual opposition to glued connections and secured journeys involving jumps. Hence, their theoretical modeling happens with the saltisitions of saltatories. Saltatories are building together with categories diamonds. What has to be risked is to stage-manage the drama of glue-free interactions and reflections within the framework of diamond theory. But metaphors like “stage” and “framework” are misleading by their unbroken coherence.

Categories: duality
Chiasms: guided complementarity or family resemblance (Wittgenstein)
Diamonds: discontectual complementarity

The epistemic tendencies “computation” and “coordination” (Fiadeiro) are thematized by the diamond strategies as complementary, antidromic and parallax. Diamonds are offering a new kind of a “metaphoric space” to distribute both tendencies while keeping their autonomy untouched. With such a heterarchic order between computation and coordination there is no need to suppress the computational aspects of coordination and the coordinational aspects of computation.

This is in contrast to the n-categorical modeling where there is no concept and no mechanism available on a principle level to implement the antagonistic epistemical directions of computation and coordination. Furthermore, both are set by the categorical approach into a hierarchical order: first computation, then coordination or the other way round: first coordination, then computation. Both are strictly excluding “social life”, i.e. interaction between computation and coordination.

2.3. Sketch of formal chiastic and diamond modeling

From hierarchy to heterarchy

Matrix modeling
**Communication** (Sender, Receiver)

- $comm_1$ as $sender_1 = put_1 \to O_2 \circ O_2 \cdot M_1$
- $comm_2$ as $sender_2 = put_2 \to O_1 \circ O_1 \cdot M_2$
- $comm_3$ as $(receiver_1 \circ receiver_2) = get_3 \from O_1 \cdot M_2$, $get_3 \from O_2 \cdot M_1$.

**Contextual modeling in ConTeXtures**

**Matrix modeling in ConTeXtures of chiasm (send, receive, pos)**
Recursivity of communication

Communication, modeled as a chiasm is not only structural but also procedural construction. contextual but distributed over different contexts, hence trans-contextual.

2.4. Costs and resources

2.4.1. Conceptual analysis

There are many ways to measure costs, efficiency and resources of computational interaction and communication.

One quite direct way might be to show the parallel, or heterarchical structure of diamond modeling and implementation in contrast to hierarchical understanding of interaction and communication. With the presumption that “parallel” processing is more cost-efficient than non-parallel computing. And obviously, it has to be shown that polycontextural and diamond computation is at least conceptually “parallel”.

Hence, using glue to organize hierarchically interaction, or even: the ‘social life’ of computing is, from the very beginning, more expensive and less efficient than heterarchical polycontextural and diamond computing.

Such considerations about efficiency and cost can be analyzed in detail for specific constellation.
Structural costs of deepness and broadness of a formula are not to be confused with the well-known complexity analyses based on computational time of big Omikron: O(n).

An analysis of the system structures of glued interaction and of chiastic and diamond interaction can be put into the simple results:
The kernel of glue-modeling consist of 3 unique instances (ports) at 1 locus (or nil), e.g. Comm = (sender₀, glue₀, receiver₀).
The kernel of chiastic modeling consist of 2 unique instances (roles) at 3 loci, e.g. Comm⁽3⁾ = (senderᵢ, receiverᵢ), i=1,2,3.
The kernel of diamond modeling consist of 2 unique instances (roles) at 4 loci, e.g. DiamComm⁽4⁾ = (senderᵢ, receiverᵢ), i=1,2,3,4.

The main difference between glued and mediated communication, i.e. between “Comm = (sender₀, glue₀, receiver₀)” and “Comm⁽ⁿ⁾ = (senderᵢ, receiverᵢ), i=1,2,3” and its mediation operation, is the fact that “glue₀” is a (coordinative) instance (object) for “(sender₀, receiver₀)” while “mediation” is a (computational) process (action) between the positions posᵢ, i = 1, 2, 3 of “senderᵢ, receiverᵢ.”

**Structural Costs**

\[
\text{cost}(X) = (n, m)
\]

n: deepeness  
m: broadness

\[
\text{cost(glue)} = (3, 1), \\
\text{cost(chiasm)} = (2, 3), \\
\text{cost(diamond)} = (2, 4)
\]

In other terms, deepness is representing computational complexity and broadness corresponds to the degree of polycontextural coordination and organization of disseminated computations.

### 2.4.2. Concept tree analysis

Concept and Kantarovic tree analyses for polycontextural constellations (formulas, etc.) can serve as a measure for structural complexity by the degree of deepness and broadness of the fundamental constructs of a situation. Broadness is the measure of the degree of dissemination, deepness is the conventional measure of the complexity of a formula. Because of their monocontextuality, broadness is set to 1 for all classical formalizations.

**Speed vs. directness**

Speed of computation is crucial for closed non-interactional computational systems, i.e. for algorithmic computation. For interactional systems directness of reaction to change of the system/environment relationship are crucial. It is clueless to finish in high speed a calculation which has become obsolete in its premises because the situation has changed. The measure for interactional systems is directness of response and not speed of calculation. From the point-view of the calculation paradigm, higher directness appears as higher speed. But that’s misleading. Directness means less steps to calculate and not higher speed. Optimization for interactional computing systems means optimizing the architectural organization to support directness.

Speed for algorithmic systems is connected with computational time, i.e. with temporalization. Directness of interactional systems is connected with organizational space, i.e. with architectonics and topology. Organization (coordination) and computation are complementary as are directness and speed.
Optimization for interactional computing systems means optimizing the architectural organization to support directness.
Speed for algorithmic systems is connected with computational time, i.e. with temporalization. Directness of interactional systems is connected with organizational space, i.e. with architectonics and topology. Organization (coordination) and computation are complementary as are directness and speed.
The Category of Glue

Is there any glue to stop the decline of Western culture?

Rudolf Kaehr Dr.
ThinkArt Lab Glasgow

Abstract

A typology of different categories of glue (ordinary, super-, para-, proto-, trans-glue) are glued together with different strategies of gluing (set and category theory, combining logics, bi-category with (co)spans, polycontexturality and diamond theory). Interpretations of “interactional glue”, “nerve glue”, “logical glue” are sketched. Keywords of the dissemination of the concept of “glue” in history (Hegel, Marx, Lenin, Gunther, Derrida, Obama) and strategies (Glue, Opium, Mediation) of gluing them together under a general parapluie (ontology, society, solidarity, fear) are critically sketched.

The economical question is: Can we still afford to glue interactions together?
The category of glue isn’t blue. Categories are clueless to interaction and are banking unsecured resources.

How good is Portuguese Glue?

The best quality of Portuguese Glue is accessible, for an affordable prize, at the Logic Shops for Combining Logics in Lisbon, Portugal.

Everything, that doesn’t fit together by nature can be glued by categorical glue. Best selling products, at the time, are the “(co)-span” articles by José Luiz Fiadeiro.

Without doubt, José’s glue, especially his “interactional glue”, is one of the most elaborated and purest form of glue on the market. Glue, today, is highly important. It always was. To feel save and gluish it is crucial to use only the finest glue available.

"We found out Portuguese glue is very good! LOL" PlanetGeorge Forums The Place George Michael Fans Call Home http://planetgeorge.org/Forum/viewtopic.php?t=3552

Such a high quality has its own tradition of expertise. Much was imported from the San Diego Zoo, California, USA. Other decisive work had been done by the scholars at place. They also had the opportunity to be guided by Brazilian specialists. As usual with success stories, there are hidden, well superseded sources, too.

Thus, the new product of combining and gluing is now available as the glue with the magic label "(co)span". To span has a temporal aspect and span is has metric determination of an inter-space or gap.

"In order to make interconnections independent of the nature of components involved, interaction protocols are formalized not in terms of morphisms (i.e. part-of relationships) but a generalized notion of (co-)span in which the arms are structured morphisms - the head (the glue of the protocol) and the hands (the interfaces of the protocol) belong to different categories, the category of glues being coordinated over that of the interfaces."

"The “semantics” of the protocol is provided through a collection of sentences - what we call interaction glue - that establish how the interactions are coordinated. This may include routing events and transforming sent data to the
format expected by the receiver.

"In this way, it is specified that components client and server are bound statically to the network nodes identified by hostc and hosts, respectively. In what concerns the connector Sync, namely its glue, our design decision was to keep it location-transparent. This choice is justified by the fact that sync does not perform any computation but simply provides a pure coordination function just like an ideal, neutral “cable”. (ibid. p.10)

This form of transient sharing can be modelled through the binary coordination connector TranSh with roles writer and reader and the glue transh.

-designed writer is
  inloc lw
  out x@lw: T
  do wr@lw:[true ¬ x:T]

-design reader is
  inloc lr
  in y: T
  do read@lr:[true ¬ skip]

The roles define the behaviour required of the components to which the connector can be applied. For a writer, we require an action that models every kind of possible operation on x. For a reader, we require an action that models the access to the input variable y. This is because it is essential to know in which location this action is executed.

The glue ensures that updates to x are propagated to y whenever the reader and the writer are in contact with each other. Whenever the communication between the two components is possible, tranSh prevents the writer from writing x before the previous change of x has been propagated to y. In the other situations, lr is not in the range of lw and, hence, y remains with the value of x at disconnection time.
On re-connection, the value of x is sooner or later propagated to y. This is achieved through the execution of the action auto that is private to tranSh and, hence, subject to fairness requirements.” (p.12)

On how Distribution and Mobility Interfere with Coordination
Antónia Lopes and José Luiz Fiadeiro

Earlier on we had to do it with buffers. Buffers are definitively quite conservative. They are conserving messages, buffers them, to help to connect different processes or even one process only, connecting it with itself.

Buffers are not only conservative but passive too. Buffers, like glue, are not computational objects with own activity but computationally inactive storage places.

Separation between computation and interaction
"This is why it is so important to put the notion of interaction at the centre of research in software-intensive system modelling, and to support methods and languages that separate interaction concerns from computational ones.” (p. 194)

"In the past, we developed a categorical framework supporting the separation between “computation” and “coordination” as architectural dimensions in software development [9].

Because we want the application of interaction protocols to be “agnostic” to the nature of the computations that are performed by the peers, we want that the protocol be based on the interfaces that components have available for
interacting with each other, not on the computations that they perform locally. This suggests that the interactions
should be established between objects of a category of interfaces, not between behaviours.” (p. 195)

"The extension is motivated by the fact that, whereas we want the interaction protocol to use a rich formalism to
specify the coordination mechanisms superposed by the glue, its interfaces should be purely “syntactic” so as to
avoid any assumption on the computations performed by the entities being interconnected.” (p.207)

Like buffers, glues are important procrastinators. They stop the direct interaction between agents to secure
message passing.

As in politics, everything has to be delayed, delegated to avoid collision of direct actions. Differences have to be
overcome by respect and solidarity. Committees are organizing such ‘generosity’ of the ruling forces in power.

On the level of artificial interaction, say between computer systems, software supported services, etc., direct
interaction has to be avoided. Computer scientists and administrators enjoy building walls and barriers between
systems or agents who are considered to interact.
Such barriers are not only separating and slowing down communication, they are also actively or sometimes
passively helping it to happen.
Buffers are one strategy, belonging to their world message passing.

Portuguese glue is another strategy. Much more modern, more general and better polished.

Nevertheless, the notion glue is not necessarily connected with the notions ‘flexibility’, ‘dynamics’, ‘liveliness’ of
interaction and the autonomy of interacting systems.

So, what is the problem?

The question is: Can we still afford to buy the glue?

Glue is procrastinating, buffering, consuming time and resources.

Do we need glue? We surely need interaction.

"This is why it is so important to put the notion of interaction at the centre of research in software-intensive
system modelling, and to support methods and languages that separate interaction concerns from computational
ones.”

That’s what the catalogs are telling us. And we agree. We have no chance to deny or reject the importance of
interaction and interactivity. For social systems and for ”soft-ware-intensive systems”, too.

There are other, serious problems involved with the social glue strategy.
Not everything can be glued together. The parts to be glued need to be structurally similar to fit together. In a
further metaphor, we cannot easily glue together water and steam or nerves and thoughts.

Also politicians want us all to glue together in the "one world, one peace, one family" eschatology. Others are
gluing themselves together into the phantasm of "one rationality, one reality, one formalism”.

Hence, glue is not only resource-expensive but also leveling and eliminating differences. Glue is homogenizing
heterogeneity.
This, easily, could be in conflict with the idea of social interaction. |
Hence, if, as in the glue paradigm, the interaction protocols of role A and role B are glued together with glueP,
then there is not much left for an interactional autonomy of A and B.

In fact, this scheme and strategy is what we are told since ever. E.g., communication theory or linguistics,
semiotics, etc., for two agents to communicate, they have to share a common sign repertoire. Or, to avoid the
danger of liveliness of multi-cultural life, you have to learn the official common language, i.e. the language of
The glue of social complexity

"The complexity involved in building the software components that will be deployed in such systems in not so much on the "size" of their code but on the number and intricacy on the interactions in which they will be involved, what in [5] we have called social complexity.

This is the motivation for studying the properties of structures of the form $<\pi A, G, \pi B>$, which we call structured co-spans. More precisely, our aim is to define and study the properties of a bicategory whose objects are signatures and whose 1-cells consist of interaction protocols."

Indeed, without the computational aspects of the glue it would not be possible to coordinate the interactions between $n$ and $m$. That is, co-spans in SIGN are not expressive enough to formalize interaction protocols.

The basic difference is that it does not make sense to see software-intensive systems as being compositions, in an algebraic sense, of simpler components. There is not a notion of whole to which the parts contribute but, rather, a number of autonomous entities that interact with each other through external connectors.

Where we differ is in the idea that there is a "system under consideration", conceived a priori, that services crossect. If we take one of the accepted meanings of 'system' - a combination of related elements organised into a complex whole - we can see why it is not directly applicable to SOC: services get combined at run time and redefine the way they are organised as they execute; no 'whole' is given a priori and services do not compute within a fixed configuration of a 'universe'.

Whereas in CBD component selection is either performed at design time or programmed over a fixed universe of components, SOC provides a means of obtaining functionalities by orchestrating interactions among components that are procured at run time according to given (functional) types and service level constraints.(deduct, p.3)

According to [2], an architectural connector (type) can be defined by a set of roles and a glue specification. For instance, a typical client-server architecture can be captured by a connector type with two roles - client and server - which describe the expected behaviour of clients and servers, and a glue that describes how the activities of the roles are coordinated (e.g. asynchronous communication between the client and the server)." (Cat, p. 158)
A bicategory \( V \) consists of:

- A class \( |V| \) of objects (also called 0-cells)
- For each pair \( < A, B > \) of objects, a category \( V(A, B) \) whose objects are called arrows (or 1-cells) and whose morphisms are called 2-cells
- For every triple \( < A, B, C > \) of objects, a composition law given by a (bi)functor \( : A, B, C : V(A, B) \times V(B, C) \rightarrow V(A, C) \)
- For every object \( A \) an identity arrow \( 1_A : A \rightarrow A \).

**Glue as a bureau d’exchange**

Interaction, not composition

"There is not a notion of whole to which the parts contribute but, rather, a number of autonomous entities that interact with each other through external connectors."

How are interactions connected?

"... a typical client-server architecture can be captured by a connector type with two roles - client and server - which describe the expected behaviour of clients and servers, and a glue that describes how the activities of the roles are coordinated ..."

interaction \( \equiv \) {entities, connectors, glue}

What is interacting? Autonomous entities!

How are activities coordinated? Glue!

Which is the expected behavior? Connector!

Interaction is understood as a composition of actions hold together by glue. Interaction, hence, is not a basic term as it should be after the proclaimed intention, but action. And inter-action is a derivative concept build by the composition of actions.

This is in correspondence with nearly all approaches to interaction (Mario Bunge, Goguen, Kohout).

David Hestenes writes in the tradition of Mario Bunge:

"The properties of things are of two general types: intrinsic and interactive. Intrinsic properties belong to the thing by itself, while interactive properties are shared with other things. The descriptors of interactive properties are called interaction variables or just interactions. A thing that acts on another thing is called the agent of the action. Two things that act on one another are said to interact. Thus, interactions (Also called connections, links, bonds, or couplings) are mutual (or shared) properties of things. Interactions influence (change or constrain) the object variables of a thing according to natural laws."

David Hestenes, MODELING is the name of the game

http://modeling.asu.edu/R&E/ModelingIsTheName_DH93.pdf
Gluing things together

- History of glue and gluing

  Glue is universal. And the glueons are holding this universe together.
  (Google offers 25,400,000 entries for glue.)

  Glutination
  Glue is a universal substance or even the substance of the universe. The activity connected to glue is gluing.
  Glutination is the category of gluing. Glutination is “The act of uniting with glue; sticking together.”
  http://www.thefreedictionary.com/Glutination

  Agglutination
  Agglutination is the clumping of particles. The word agglutination comes from the Latin agglutinare, meaning
  "to glue to."

  Glue is very closely connected with the history of mankind. Glue glued not only groups together but glued
  things together to build tools to enable groups to glue together.

  Glue is produced from nature: plants, animals, from human beings or synthetically.
  Glue is a metaphor, a concept, a name, a programming language.
  There are more than 26 million Google entries for Glue.

  ultimate glue
  "Why is sex the ultimate glue? Why is it so important in a romantic relationship? In a nutshell, sex is glue
  because it is the one that makes your romantic relationship unique from all the other relationships in your life.”
  http://drseth.blogspot.com/2008/10/why-sex-is-glue.html

  Conceptual Glue (E. Margolis 1999)

  glue - Collaborative International Dictionary of English v.0.48 :
  Glue `(glu or glu) n. [F. glu, L. glus, akin to gluten, from
  gluere to draw together. Cf. Gluten.]`
  A hard brittle brownish gelatin, obtained by boiling to a
  jelly the skins, hoofs, etc., of animals. When gently heated
  with water, it becomes viscid and tenaceous, and is used as a
  cement for uniting substances. The name is also given to
  other adhesive or viscous substances.
  [1913 Webster]

  Gluing.] [F. gluer. See Glue, n.]`
  To join with glue or a viscous substance; to cause to stick
  or hold fast, as if with glue; to fix or fasten.
  [1913 Webster]

  “This cold, congealed blood
  That glues my lips, and will not let me speak.” - Shakespeare.
  [1913 Webster]
  http://onlinedictionary.datasegment.com/word/glue

  Next to the material history of glue and the techniques of gluing there is also a short story of conceptual glue and
  gluing.

  Hegel
  "The 'glue' that binds the world together is, in Hegel's view of the matter, not the eternal falling apart of
  objects, but simply their necessary interconnectedness; if you attempt to separate them, they will not stay put.
  Nor is it that negation which disintegrates the universe that Hegel uses as the 'mortar' to combine it; it is that
negation which, because it is as much positive as negative, does actually combine it. After all, it would appear that one is forced to admit that Hegel is more than a superficial thinker trying to palm off on a long-suffering public palpable absurdities.”
http://www.gwhegel.org/Books/TR3.html

**Marx**
"Religion is the sigh of the oppressed creature, the heart of a heartless world, and the soul of soulless conditions. It is the opium of the people."

Religion: The Glue That Binds Society Together".

**Lenin**
"Die Religion ist das Opium für das Volk. Die Religion ist eine Art geistigen Fusels, in dem die Sklaven des Kapitals ihr Menschenantlitz, ihren Anspruch auf ein auch nur halbwegs menschenwürdiges Dasein erschaffen."
http://www.vulture-bookz.de/marx/archive/quellen/Lenin~Opium_fuer_das_Volk.html

**Sniffin’ Glue: the Essential Punk Accessory**
"The Baiti association says 98% of children living on the streets in Morocco are now addicted to sniffing glue and the number is growing.”
http://news.bbc.co.uk/2/hi/africa/4113441.stm

**Money**
"Money as the medium of exchange is the glue of society, for society is sociated by human action, by human practice in living with one another. Monetary value is abstract usefulness which is understood by human understanding within the practice of trading, i.e. commodity exchange, and thus ‘holds everything together’.”
http://192.220.96.165/untpltcl.html

**Heidegger**
Heideggerian continental philosophy and naturalistic cognitive science need not be mutually exclusive and shows further that a Heideggerian framework can act as the "conceptual glue" for new work in cognitive science. In _Reconstructing the Cognitive World_, Michael Wheeler
http://www.citeulike.org/user/TomQ/article/3444021

**Gunther’s Hide Glue**
I haven’t found any glue in Gunther’s work. In a dialectical and cybernetical turn, Gunther calls what others would call glue “mediation” (Vermittlung). His _Theorie der Vermittlung_ is realizing a tabular connection of complexity and complication of logical systems (place-valued and context-valued logics) with over-/under- and balanced constellations. The complexity of holding together is hidden by the _Hide Glue_ and well fibred by _Fibrin Glue_.

**Heinz von Foerster**
“The question of applications in the social sphere was a problem to which I was attracted quite early on. I and my friends always regarded the social problem as having to do with the possibility of a linguistic connection. We saw language as the _glue_ that forms a society. […] Language makes second-order communication possible.
http://bcl.ece.uiuc.edu/mueller/index.htm#ftn45

**Derrida:**
Harold G. Coward, Toby Foshay, Jaques Derrida:Derrida and Negative Theology, 1992, § The Deconstruction of Buddhism
"It is because we see the world as a collection of discrete things that we superimpose causal relationships, to “glue” things together.” David Loy, p. 247

**Glue, a challenge**
"Tabbi: Could you deconstruct Glue for me?
_Ulmer_: One of the first things that fascinated me about Derrida was the theory of the signature. The relation of the proper name to individual historical experience was an obvious place to test some of the poststructural claims about the place of chance, (non)motivation of language, and the like. The experiments that led to mystery and choragraphy began with the exploration of my own signature. Notions of fate have given way to the constructed subject; but still the proper name provides an anchor, a ground upon which identity may constellate.

"In Glas Derrida devotes considerable attention to the phenomenon of agglutination, and speaks of the gl and
the glue.

"This theory resonated with the phrase used by peers to tease me in grade school (generating Elmer's Glue from Ulmer). My interest in arts using collage equaled my interest in theory; the art of collage has been defined as the art of gluing. One negative review described Applied Grammatology as sticking to Derrida like glue.

My initials are G.L.U. + the French silent e. The properties of glue are suggestive of my concern with group formation, with a certain kind of community creation. I have not done a full examination of the vehicle. I use glue online, usually in a MOO setting, but also in e-mail. Students often remind me about how glue is made. I have not thought about the implications of that yet."

Glus, 195-196b
by Jacques Derrida
"I forgot. The first verse I published: 'glu de l'étang lait de ma mort noyée' ('glue of the pool milk of my drowned death')."

And for people like us:
"Fear is the glue that binds these structures."

Moreover, since philosophy is the glue, the deep structure, that holds so many things together, its critique has ramifications that open up numerous areas of struggle. p.195

Web 2.0: Obama
Obama: "I'm rubber. You're Glue. Whatever you say...."
Rubber and glue
Super glue

Glue2.0
"You are summing up exactly the value of Glue - semantics is on the background doing its magic, but the really important thing is new way for people to connect - in the context, without friction."
http://getglue.com/

More glue
glue - Free On-line Dictionary of Computing (26 May 2007) :
<jargon> A generic term for any interface logic or protocol that connects two component blocks.
For example, Blue Glu is IBM's SNA protocol, and hardware designers call any thing used to connect large VLSI's or circuit blocks "glue logic" b(1999-02-22)
http://onlinedictionary.datasegment.com/word/glue

Like glue, too.
http://uk.youtube.com/watch?v=iLQ__fc7_jU

Semiotic glue
"... he plays well but, man!, with the WRONG technique
the piano is the most stationary of instruments, if one excepts the church organ
the chords played are just plain UGLY
the ladies morning musical club would be shocked
you need a kind of semiotic glue
i was lamenting about the fact that maybe the surface was TOO dissonant call it fauré, call it sorabji..."
http://pages.infinit.net/kore/contrepoint.html

A glue language is a programming language (usually a scripting language) used for connecting software components together.

Glue semantics. Glue logic.
Nerve glue.

**Tautological glue**
"The cultural glue that holds America together, *Bertrand Russell* said, is Americanism."

**Cultural Glue**
"Digital codes work as cultural glue through space and time."
http://www.nbi.dk/~emmeche/coPubl/91JHCE/codedual.html

**Glue or Cement?**
"Normally, an organization consists of an architecture being the *cement*, or the *glue* between many agents. The levels of complexity of architectures and agents define the complexity level of the organization. Agent sorts can be discerned regarding the presence or absence of the following components: perception, interaction (including learning in the sense of habit formation), representation (including learning in the sense of chunking) and autonomy."
http://www.rug.nl/staff/h.w.m.gazendam/semiotics_multi-agent_systems_and_organizations.pdf

**From glue to gluons**
"These forces, which "glue" the quarks together in "white" bundles, are mediated by field-quanta that are called *gluons*, which like photons are massless spin-1-particles. As a force between two quarks act between 3-3 colour-combinations, one should think there would be 9 different gluons, but it turns out that the photon is hiding among these combinations, so there are only 8 gluons."
http://www.library.utoronto.ca/see/SEED/Vol3-2/Christiansen_3-2.htm

Or simply: GLUE

Glue from animals, from human beings or synthetically. But there is also mental glue, conceptual, structural and algorithmic glue.

The glue of language. The language of glue. Language as glue and glue as language. The language GLUE.

And finally:
**Glue** is a novel by Scottish writer *Irvine Welsh*.
"Glue tells the stories of four Scottish boys over four decades, through the use of different perspectives and different voices. Glue addresses sex, drugs, violence, and other social issues in Scotland, mapping "the furious energies of working-class masculinity in the late 20th century, using a compulsive mixture of Lothians dialect, libertarian socialist theory, and an irresistible black humour." The title refers not to the abuse of adhesives, but the metaphorical glue holding the four together through changing times."

It's a never ending story. At least: There is no mankind without glue.
Scots are spelling glue as "glu" with a long "i", hence ‘glüh’. Like in German: "Glühbirne". There is without doubt a lot of linguistic glu(e) between glüh and glue. One is called *Scottish Enlightenment*.

The real story is here:
http://www.taz.de/1/zukunft/umwelt/artikel/1/verehrt-verraten-und-verglueht/

**Glue as Leim**
Nevertheless, the whole story of Glue would get a different turn if it would be told in German language, with the help of the key words: Leim, Schleim, Heim, Keim. Verbindung, Binder, Blinder and Kleber.

A strong linguistic neighbor of glue is "clue". The glue of cryptography.

"Glue everywhere. As Bertrand Russell cleverly put it in one of his treatises, glue is a very sticky business."
http://judgemental.merseyblogs.co.uk/2007/08/someones Been court out.html

**Typology of glue**

Glue is gluing. It glues things or persons or thoughts or whatever together. There are some degrees of distinctness in the process of gluing to observe.

Parts to be glued might belong to the same category of things. They might be of the same ontological species.
Such a species might be concrete, like classical objects, or it might be abstract, like classical concepts or models. Such an approach is well modeled by set theoretical concepts.

If the focus is more on the inter-relation between things and concepts and not as much on their content, category theoretical concepts and methods are well applied.

Both approaches, set and category theory, are belonging to mono-contextural thematizations. Both are based on simple dichotomies: element/set and object/morphism both belonging to one and only one universe or “conglomeration”, hence mono-contextural.

If things are slightly more different and not automatically commensurable, bi-categories are at place. They still are at home in one universe. And their gluing power is restricted to glue together the two categories of bi-categories. Or later, for more complex constellations, n categories of n-categories. Still, under the umbrella of a unifying conglomeration. Hence, in fact, super-glued by the unique conglomeration.

Set theory and category theory are working with ordinary glue, called first-order glue. It would be unfair and misleading to call it super-market glue.

Because things, interactivity, are highly dynamic, different levels of consistency and coherency of the state of glue have to be considered:

hard vs. soft,
stable vs. elastic,
uniform vs. gasiform,
constant vs. scaling,
etc.

Interactivity is an ever-changing event, glue has to be able to adapt to the changing circumstances of gluing actions together.

The super-glue of n-categories is gluing together the gluing power of 1-categories.
For both, the rules of the gluing power are simple: No glue is a glued, and no glued is a glue. TND.

Advise how to use superglue
http://www.metacafe.com/watch/46663/super_glue

Polycontextural theories are more split and poly-phrenic. Awful things happens. Not only there is differentness between conglomerations to be glued, there is also no glue that could glue together such conglomerations, that are, as it was mentioned, the umbrellas for n-categories and their own gluing strategies. Much worse, what is gluing conglomerations together might turn out to be itself a conglomeration and conglomerations might play the role of glue. Such a non-glue glue isn’t a superglue nor a crazy glue.
But a proto-glue, the glue before the glue, in general. What’s before the glue is the abyss. And proto-glue is the jumping device to jump in-between the gaps of differentness, hence its real market-label is trans-glue, the glue beyond/between the glue.

Proto-glue
"Like Ozu’s later An Inn in Tokyo, this one is at its best when it proceeds to indulge in moments of a proto-glue sniffing aesthetic, which is essentially my own term for gritty and surreal (think Herzog) moments of humor."
http://cinematalk.wordpress.com/2008/07/21/

In the case of diamond theory, not only the well known types of glue, like glue-glue, meta-glue, super-glue, proto- and trans-glue, are gluing glues together but, at once, antidromically, to each gluing, of whatever type, there is also an un-gluing gluing gluing.

First-Order Glue

"Glue has evolved significantly during the past decade.”
"Glue (Dalrymple, 1999), a compositional semantics framework based on linear logic (Girard, 1987) has evolved over the years.”
Miltiadis Kokkonidis, Glue as the Syntax-Semantics interface
http://users.ox.ac.uk/~lina1301/Kokkonidis06c_icttl_simplefog.pdf

Meta-level gluing
1st-order gluing
Gluing of elements, sets and also gluing of categories shall be called 1-order gluing, i.e. ordinary or real gluing.

2nd-order gluing
N-categorical gluing shall be called complex gluing, i.e. gluing complexions of different categories, hence 2-order gluing.

3rd-order gluing
Polycontextural gluing shall be called second-order gluing, i.e. trans-gluing, hence 3-order gluing. The French may call this stuff trance-glu(e).

4th-order gluing
Diamond gluing shall be called splitting-gluing, i.e splitting the glue of gluing the glue, hence 4-order gluing.

Para-glue is the parapluie of all umbrellas without being itself an umbrella. It guarantees a state of gluey gluishness.

Theories of conceptual glue

- Set theory

Set theory is working with ordinary glue. One big universe of sets is enough to glue all the sets together. Who, who wants more gets punished by antinomies. Others will have to climb the ladders of Bertrand Russell’s escape strategy. In ordinary mathematical life ordinary glue is enough, it is doing its job of gluing things together properly.

Claude Shannon’s glue

“Irish glue has the reputation with some persons.”

With the mathematical theory of communication, the communication model needs a common sign set as a cut of the sign repertoires of two communicants, sender and receiver or source and target. Such a cut is representing the common ground of communication. It functions as the necessary communicational pool of pre-giveness without it no communication can be realized.

Mostly, this obvious triviality isn’t mentioned at all. Communicants are supposed to communicate directly and successful against the disturbance of the channel by noise.

As an example of an explicit semiotic model of communication, which is considering a common pool of knowledge the following diagram may visualize the role of the pool. In fact, it is a set theoretic intersection between the pool of the source and the pool of the target.

Hence, without intersection (overlapping), no communication. Intersections are easily done, without any trouble, with the help of Cantor’s glue.

Fig. 5. General model of communication

"As the communication model is presented here (cf. Fig.5), it also incorporates modifications which do not stem from the Prague school. According to an idea, suggested both by Moles and Lotman, the
sender and receiver of any situation of communication start out with “codes” — or, as I would prefer to say, systems of interpretation —, which only partially overlap, struggling to homogenise the system of interpretation as the communication proceeds (cf. Sonesson 1995; 1997c).

The communicative act is said to be **sender-oriented**, to the extent that it is considered to be the task of the receiver to recover that part of the system of interpretation, which is not shared between the participants.

It will be **receiver-oriented**, to the extent that the task of recovering knowledge not held in common is assigned to the sender.

When sender and receiver fail to **negotiate** the parts of the interpretation system which they do not both possess, the resulting concretisation will be a **deformation**.

### Strategies to avoid glue: Hidden Glue

Strategies to avoid glue are well known.

One of them is best summarized for computing models and programming languages by the strategy "EverythingIsa: Everything is a EverythingIsa."

This method of gluing things together without getting wet and glued or agglutinated is applied for cosmological, social and biological theories too. It is the strategy of avoiding glue with the help of a hidden ultra-super glue, sometimes properly called **Deus Absconditus**.

The Class of all classes.
The Category of all categories.
The Module of all modules.
The Macro of all macros.
The ETC of all etc.

The other strategy, not yet well known in scientific circles and programming labs is: **Barr the barr**. Or equivalent: **Don’t barr the Barr**.

Albeit an ancient strategy, it is used and becoming fashion only recently.

The main Barr barrer is the thinker Martin Heidegger with his barred non-term-terms Sein and Ereignis from his writings.

"Insofern kann ‘Ereignis’, bezogen auf diese Systeme, nur *gebarrt* geschrieben werden: **Ereignis.**" (Peter Fuchs)

(FrameMaker offers the function “Strikethrough”)

EverythingIsa: Everything is a EverythingIsa.

Categories and Contextures

Peter Fuchs: Ereignis, Welt und Weltereignis
### Category theory

Category theory, which doesn’t want to be involved with the internal’s of sets, is interested more into the inter-relationships between so called objects. Such inter-relating morphisms are building a society of objects. What is the glue of this society of objects? The glue of this society is not Opium but coincidence. Coincidence relations as matching condition are gluing morphism together. Without such glue there is no commutativity for the composition of morphisms. Compositionality as such remains an open question.

Category theory as the general glue of mathematical studies.

In other words, the conditions of the composition of morphisms, i.e. the coincidence between codomain (target) and domain (source), or the matching conditions of mappings for the 'object-free' category are not themselves defined by categorical notions.

This sounds trivial, because the matching conditions are defined in a logical meta-language. But the interactivity between the categorical object-language and the defining meta- or proto-language isn’t clear.

"For him [Jean-Yves Girard], category theory characterises objects in terms of their "social lives"."  
José Luiz Fiadeiro, Categories for Software Engineering, p. 2

Combining: splitting/slicing
Where there is no glue there are bridges.
Combining logics

"By ‘bridge principles’ we mean, in a wide sense, any interactions (i.e., derivations) among distinct logic operators which are not instances of valid derivations in the individual logics being combined.

"Therefore bridge principles are the result of reciprocal action or influence of the collective logics being combined, and not merely derived rules or theorems."
http://www.cle.unicamp.br/cle30-ebl-slalm/TutorialEBL01.pdf

Glue logic
"Glue logic is a theory of 'semantic assembly', that is, the way in which information about the meaning that is provided by lexical items and grammatical constructions is put together to get a meaning for the whole utterance.”

Adhesive categories
Stephen Lack and Pawel Sobocinski: We introduce adhesive categories, which are categories with structure ensuring that pushouts along monomorphisms are well-behaved. Many types of graphical structures used in computer science are shown to be examples of adhesive categories. Double-pushout graph rewriting generalises well to rewriting on arbitrary adhesive categories.

"This provides further evidence of how pushouts behave in adhesive categories as well as making more precise the intuition that the pushout operation "glues together" two structures along a common substructure. As a corollary, it follows that in an adhesive category the lattices of subobjects are distributive.

"Definition 5.2 (Gluing Conditions). Given a production p as in (1), a match in C is a morphism $f: L \rightarrow C$. A match $f$ satisfies the gluing conditions with respect to $p$ precisely when there exists an object $E$ and morphisms $g : K \rightarrow E$ and $v : E \rightarrow C$ such that

$L \leftarrow K$
$f\downarrow v$
$4g$
$C \leftarrow v$

is a pushout diagram."(p. 15/16)
http://www.brics.dk/RS/03/31/BRICS-RS-03-31.pdf
Bi-category theory

From glu(e) to (co)span.

A span, even a co-span isn’t yet a salto.

Typically, in a category of systems, morphisms capture a “component-of” or “sub-system” relationship. As already motivated, in software intensive systems it does not make sense to talk about “component-of” relationships in an algebraic way.” (CALCO’07, p.195)

Glue is a crucial term in the work of José Luiz Fiadeiro. Also the term “glue” isn’t honored in the index of his “Categories and Communities” eBook. The term “glue” nevertheless occurs 36 times at strategic positions.

IGLU, as a white box of gluish mediation

"The other structure that is important for interaction protocols is that of the glues; we assume that glues can themselves be organised in a category IGLU and that a functor sign:IGLU->SIGN returns, for every glue, the structure of interactions (signature) that are being coordinated by the protocol. As a consequence, a morphism σ:G1->G2 of glues captures the way G1 is a sub-protocol of G2, again up to a possible renaming of the interactions and corresponding parameters. That is, σ identifies the glue that, within G2, captures the way G1 coordinates the interactions sign(G1) as a part of sign(G2). In fact, because we need to be able to compose interaction protocols, we assume that IGLU is also a finitely co-complete category. (J.L. Fiadeiro, Schmitt, p.200)

"That is, sources of morphisms in diagrams in IGLU are, essentially, signatures, which is why we decided to work with structured morphisms in interaction protocols. (ibd. 201)

Nevertheless, things are highly intriguing:

"More precisely, given a coordinated category sign:IGLU->SIGN, using cospan(SIGN) for interconnections is too poor because it does not support the definition of coordination mechanisms, and using co-span(IGLU) is too strong because the interfaces involve computational aspects. This is why we proposed to work over an algebraic structure co-span(sign) that is based instead on sign-structured morphisms." (p.14, CALCO’07)

There is a big and a small iglu included: iglu:SIGN->IGLU.
Polycontextural logic

Ferdinand de Saussure: glue/clue

Mediation of different contexts is glue-less. Glue is clueless to mediation. Glue, as we know it from category theory is not a mechanism, it is a non-mechanism of suggestiveness. It suggests solutions where there are nothing more than desires. Glue turns out to be a universal blank, a fashionable legerdemain of domains and codomains.

Gotthard Gunther tried in his early philosophical attempts to get rid of the hallucinogenic, glutinous, adhesive sizziness of the ultimate clamminess of social-ontological considerations.

First, in the early 30s he discovered the conceptual mechanism of mediation in Hegel’s Logic. Then he tried to glue together his discoveries with the then arising mathematical logic, especially the early work of Alfred Tarski.

After his emigration to the USA, he tried to work out the logical mechanism of mediation. First, as a multi-valued place-value system of logic culminating in his general logical theory of mediation (Vermittlungstheorie) of different trans-classic types of logics. Then as a morphogrammatically based quindecimal system of mediation.

There was still a lot of glue necessary to let the mechanism of mediation run. But because of its imminent processuality, mediation isn’t to fix by any glue.

Only a brand new procedure of evaporating such mediating glue led to a more clamminess-free running of the mechanism. The sacrifice was enormous and radical: he had to eliminate any kind of conceptual and apparative lubricant of onto-logical heritage. This glue-free mechanism, called morphogrammatics, enabled a kind of a first run of clean and pure mediation of logical systems as a basic framework for cybernetic, cognitive and volitive, conceptual designs.

Where there are no objects and no inter-relating morphisms in the play there is also nothing which could be glued.

Such morphogrammatic mechanisms are based on the inscriptions of emptiness, called kenograms. The situation established is not specifically gluish, there is not much academic gossip possible about and of the ultimate but structured emptiness of the void; but the mechanism is working in its dry silence.

It may still be an open question if such sacrifices are strictly necessary to get rid of the self-fumigation of current glue-strategies in computer science not to mention the bulk of social theories in sociology and informatics.
Diamond theory

Agglutination, inversion, chiasm: "gl" and "lg".

Complementarity of categories and saltatories is interplaying in a glue-free game of jumps. Categories might be glued. Saltatories are not gluing their gaps. Complementarity between categories and saltatories happens in a glue-free interplay of bridging salti.

In other words, how can we glue things together without getting hassled by the clamminess of our glue and still being able to enjoy the gluishness of its intoxication?

The answer to this paradox is given by the jump-operation of saltisitions.

Saltisitions and hetero-morphisms are characterized by antidromic orientations. Hence, it would be natural to think of them as products of inversion, i.e. as inverted morphisms. But that's not a solution. The inversion of "glue" is "ugly", and there is no doubt that glue is fundamentally ugly and a categorial member of ugliness.

A combination of the ag- "gl" and de-glutional "lg" to "gl-lg" is discovering a tiny chiasm in the very concept of the ugliness of agglutination (GLAS, Derrida). This phenomenon probably was the very reason that let to the misleading hope that the mechanism and strategy of inversion and dislocation of (semiotic) gluton will help to avoid the crash of the evaporating glue of togetherness.

Saltisitions are inscribing the conditions of the possibility of categorical compositions. Compositions in category theory are glued together by the matching conditions. Their clamminess might be avoided by a jump from category to diamond theory.

First, the categorical gluing operation is mirrored in its complementary hetero-morphism. Hetero-morphisms are reflecting, complementarily, the compositions of categories by keeping their concept of compositionality while avoiding their clamminess.

Second, by the complementarity of categories and saltatories the clamminess of the matching conditions for compositions gets its complementary counter-part in saltatories as the glue-less jumping operation between hetero-morphisms. Saltitions are freed of any resemblance to glueness. The glue has evaporated into the joy of jumps.

Third, Diamond theory is thematizing the activity of the composition operator not as a morphogram but as a complementarity to the operator, implemented as a hetero-morphism. Diamonds are thematizing the basic operation of category theory as such: the operation of composition. The thematization is modeled into the hetero-morphisms. In a general setting of graphematic analysis of composition, the morphogrammatics of the operator "composition" has to be taken into account, too. That is, the neither-nor gesture of categorical object and morphism has a double face: hetero-morphism and morphogram of composition.

Forth, Composition-free interplay. In a kenomic play (Fink, Derrida) there is no composition, neither any "gl" nor "lg" mispend.

Diamond theory of interactivity

This part of the Short Study "Category of Glue" will be glued together as soon as I have found the "gl"/"lg"-free glue of ugliness and shall be published as part II of "Category of Glue".
Luhmann’s secret diamonds

New entries for the Zettelkasten

Rudolf Kaehr Dr.@
ThinkArt Lab Glasgow

Abstract
A kind of a similarity between Luhmann’s concepts of sign, system, difference and re-entry and the main figures of diamond theory is observed.

1. Where are Luhmann’s diamonds?

1.1. Citations

"When a communication constitutes a previous communication as a communication, it simultaneously distinguishes it from all those other things in the world that are not communication. In this sense, all operations of autopoietic systems always distinguish the system and its environment.

"Distinctions, however, are observations that constitute a difference between two sides and thereby relate these sides to each other. Observations, which are thus the application of distinctions, 'open' the system for conditions of the environment, but as internal operations they 'close' the system by distinguishing it from its environment (1997a page 92^108).
An observation relates and differentiates: it is a unity of difference.

"Its main cornerstones are a conception of space as the possibility of drawing distinctions, and an analytical focus on accessibility systems and organisations.”

Martin Gren, Wolfgang Zierhofer: The unity of difference: a critical appraisal of Niklas Luhmann's theory of social systems in the context of corporeality and spatiality
http://www.envplan.com/epa/fulltext/a35/a35280.pdf

Self-referentiality of distinction

Social systems are constituted as „self-referential objects. We can observe and describe these as systems only if we accept that they refer to themselves in every operation' (Luhmann, 1995, page 437).

Components of distinction: indication and distinction

"However, there is a fourth point that will occupy us at least for a short while. I have already alluded to it. Spencer Brown’s theory design contains a well-hidden paradox. It is constituted by re-entry itself or— if we refer to the beginning of the calculus, the first injunction 'Draw a distinction!'—by the fact that the distinction must be and is drawn merely in order to distinguish one side. Thus, every distinction contains two components: indication and distinction. The distinction contains itself, but apparently in a very specific form: namely as the distinction between distinction and indication, and not merely some juxtaposition such as of large and small, or anything else that could be conceived of as a distinction." Luhmann, p.19

Consecutivity as a reason for time and memory

"When a system constitutes itself, it draws a difference between system and environment by carrying out two subsequent operations: distinction and indication (Rasch and Wulf, 2000, page 36).
First it distinguishes two sides and then it indicates one of these sides as the system (or the observer). As these operations are consecutive: they constitute or 'consume' time. All observations are thus temporal: one cannot be on both sides of a distinction at the same time. Introducing a difference in time is one of the operations that autopoietic systems use in order
to 'unfold' (or solve) the paradox of reentering distinctions (or the self-application of a code).” (Martin Gren, Wolfgang Zierhofer, ibd)

“To cope with these consequences of a re-entry of the internal/external difference in itself, the system needs and constructs time. It needs a memory function to discriminate forgetting and remembering. Its past is given a highly selected present and, in this sense, a reality” (Luhmann, in Rasch and Wolfe, 2000, page 37).

**Binary codes**

"From the point of view of the system, its binary code is universally valid because it may be applied to all its objects: for example, to all statements (science) or to all actions (law). Binary coding excludes third possibilities, and, as soon as the code is applied to itself, either tautologies (‘true is true’) or paradoxes (‘true is not true’) are produced. Therefore, the binary code must not regulate its own application. This is instead the task of programs (Luhmann, 1989, pages 37, 39 40, 45).” p.5

### 1.2. Interpretation

It seems to be more fruitful today to thematize and formalize Luhmann’s distinctions with the help of diamond theory instead of the Calculus of Indication of George Spencer Brown.

A key notion in Niklas Zettelkasten, obviously, is self-reference.

The other crucial notion is the self-referential concept of difference.

With that all kind of connections to logical, methodological and epistemological considerations are provoked. A strange connection to Spencer-Brown was inaugurated, mainly by the influence of Heinz von Foerster. The re-entry figure became a machina creativa, albeit nobody had a training in formal languages at all.

**Difference and relation; différance**

But Luhmann’s work is about social theories and not about logic. Neither is Luhmann’s theory of social systems a semiotic or semiological theory. This point is not yet well understood. Semiotics, but the French “sémiologie” too, are based on relations, triadic for semiotics and dyadic for semiology. But Luhmann’s concept of a self-referential and “therefore”, paradoxical concept of difference isn’t based on relations but on difference (Unterscheidung). Relations are presupposing difference, and are thus secondary to the paradox concept of difference. Relations are logical and not paradoxical.

Derrida has given strong deconstruction of the semiological and semiotic sign concept and its relational foundations in logocentrism. With his radicalized interpretation of de Saussure’s semiology, he transformed the concept of difference to the paradoxical non-concept of différance. The difference of the difference, the différance, is not in a relationship to relations.

Similar, Gotthard Gunther’s non-concept of proemial relationship.

Hence, Luhmann’s insistence on self-reference might well be reformulated in different ways. One, which I proposed for many years, is interpreting self-reference and its circularity in the framework of a polycontextural understanding of chiasms, i.e., technically, as proemial relationships.

Now, after this chiastic theory got some maturity, albeit not much recognition, it is time to introduce the diamond approach to difference and circularity of system and environment. Diamond strategies are a further radicalization of the earlier approach of polycontextural chiasm.

Also Luhmann’s work is not well known in the Anglo-Saxon world, it isn’t a wrong feeling to observe that also the themes and topics, and their highly reflected treatment by Luhmann, has no real existence in the world-leading sociological literature of the super-power theoreticians.

### 2. Supplementing the Zettelkasten

It doesn’t seem too risky to risk an interpretation of Luhmann’s theorizations out-side or beyond second-order cybernetic figures and metaphors.

In other words, is there a strict necessity to understand Luhmann’s adventure in terms of his entries of his own Zettelkasten?

Is it possible to ‘re-construct’ his constructivism and re-enter into it without its terminology and jargon of difference, distinctions, re-entry and self-referentiality?

Luhmann’s theory is self-referential, thus it could refer to itself in different terminological modi, and still
keeping its adventures strategies and networks of constructing a de/constructive theory of social systems alive.

Hence, I will take the risk to supplement the Zettelkasten by smuggling some non-contents of diamond boxes into this, now electronic, Zettelkasten.

By re-reading the passage with its introduction of the difference of system and environment, I think that I’m observing, or as I prefer to say, hallucinating some features not yet been recognized and mentioned, neither explicitly by Luhmann nor by his followers.

Self-referentiality without referentiality?

The rhetoric figures of Luhmann’s texts are not necessarily determined by the frameworks of the used technical weaponry. The cage of the jargon is not necessarily incarcerating the dynamics of the gesture.

Technically, I try to understand Luhmann’s theory of social systems from the viewpoint of polycontextural and diamond systems. Hence, I try to avoid to go into the litany of second-order cybernetics, systems theory and Spencer-Brown’s Calculus of Indication and its extensions.

Even more technically, my interpretation of Luhmann’s gestures with the introduction of his rhetoric figures is due to a morphogrammatic subversion, abandoning any jargon and terminological content, as crucial as it might be, and conceiving the dynamics of the pattern, only.

After this new diamond approach is introduced, experienced and further developed, a renewed lecture of Luhmann’s work as involved with the above mentioned second-order trends, might happen again.

The term “diamond” refers to itself, only. There is no reference to exposed marketing labels necessary.

2.1. Binaries

Communication/distinctions
system/environment
Observations: open/close
relate/differentiate
space
Open/close are inverse operations

First, the system is the difference between system and environment.
Second, the system can be defined through a single mode of operation.
Third, every (social) system observes internally (i.e. within the system) its own system/environment distinction; there is a re-entry of the system/environment distinction into the system.
Fourth, every social theory is part of the social domain and as such part of what it describes.

Systems exist.
Obviously, this is a paradoxical formulation. And only academic blindness can deduce that it is a confession for ontological realism.

2.2. Uncovering Luhmann’s diamonds

Statement
"When a communication constitutes a previous communication as a communication, it simultaneously distinguishes it from all those other things in the world that are not communication. In this sense, all operations of autopoietic systems always constitute the difference between the system and its environment"

How can this happen? If an operation of an autopoietic systems is producing by its action, i.e. operation, both, the intended operation and at the same time, the operation of distinguishing the system of the first operation from its environment, then it “constitute[s] the difference between the system and its environment”. How is an autopoietic operation simultaneously operating in its domain (system) and producing an environment of the domain? Or in other words, how is an operation operating that it is able to operate and thereby by such operation constituting (operating) its own environment?

The first answer, which might be given by Luhmann is the hint to Spencer Brown’s Calculus of Indication: “Draw a distinction!” With this distinction, the ‘world’ is ‘divided’, i.e. ‘distinguished’ into two parts, the inside and the outside of the ‘world’ or ‘space’.

But what is given by the CI? ‘Two ‘equations’.
In this formulation, no world appears. The world or space is presupposed and realized by a sheet of paper or
another medium of inscription. This might be interpreted cognitively by a user of the CI. And this interpretation will become a meta-theoretical environment of the calculus. But nevertheless no part of the calculus in question.

Again, "*When a communication constitutes a previous communication as a communication, it simultaneously distinguishes it from all those other thing in the world that are not communication.*"

**Interpretation**

"*When a communication constitutes a previous communication as a communication*"

This is involving several procedures:

1. "*communication constitutes a previous communication*", this might be naturally understood as a composition of two communications.
2. "*as a communication*" means, that the composition has to be realized as a composition of communications and nothing else. But this condition is exactly what is called the 'matching conditions for compositions'.
3. With this formulation we get a clue to understand what could be meant by the consequence: "*it simultaneously distinguishes it from all those other thing in the world that are not communication.*"
   This consequence of the composition of communications is following consecutively the 'assumption' of the operation of composition albeit it states its *simultaneity*.

**Diamondization**

Luhmann's communicational statement, the 'axiom' of communication, interpreted as a categorical composition of communications offers a natural introduction of the otherness of communication, i.e. the simultaneous environment of communication by the saltatorical hetero-morphisms.

It needs two communications to realize communication and its environment as the singular otherness of communication. This asymmetry is directly covered by the saltatories of diamond theory, which are complementary to the categories of communication.

Because of the operativity of the diamond interpretation of Luhmann's conception of communication, communication might now be studied operatively on all levels of complexity and complication necessary, together with their interplay.

This diamond interpretation is not reducible to the indicational calculus and its use for autopoietic and communicational systems.

Again, what are the conditions for communication? Communications have to be "anschlussfähig", i.e. they have to fulfil the conditions of connectivity.

In category and diamond theory, such conditions are exactly the *matching conditions* of composition.

Now, there are two possibilities opened up.

One insists that the conditions of the possibility of something are not identical with such a conditional something.

The other position could take a highly formalistic turn towards self-referentiality and postulate that there is no logical difference between the conditions of something and such a something.

Without doubt, the latter position leads with logical paradoxes. But who cares?

Why should we use logic? And which logic anyway?

It also could be mentioned that the comparison itself is too much restricted by logic and alternativity.

The first position sounds harmless if we take the statement in a hierarchical way, i.e. if we postulate a sequential order between the conditions and the entity. But why should we accept this decision as the only working possibility?

The diamond approach, obviously is postulating a simultaneity of both thematizations, the conditions of the possibility and the characteristics of the entity.

It might be a question of taste which of both positions has to be considered as more crazy: the ultra-formalistic or the diamond approach.

**Re-entry and in-sourcing**

"*To cope with these consequences of a re-entry of the internal/external difference in itself, the system needs and constructs time.*" (Luhmann)

Again, in-sourcing:

"*The idea of in-sourcing the matching conditions into the definition of diamonds seems to be in correspondence with the two main postulates of "Chinese Ontology", i.e., the permanent change of things and the finiteness or closeness of situations. That is, diamonds should be designed as structural explications of the happenstance of compositions and not as a succession of events (morphisms).*"
The figure of re-entry tries to correspond to the device to include "the internal/external difference in itself". This happens in "consequences" and needs/constructs time. Hence, the idea of a simultaneous realization of the difference of system and its environment gets lost in the infinit delirium of self-reference.

In-sourcing the matching conditions of composition is a finite and simultaneous constellation of categories and saltatories. It is the interplay of both, categories and saltatories of a diamond constellation, which is realizing the figure of re-entry in a finit and differential manner. Both strategies, the re-entry and the in-sourcing, seems to correspond to a similar gesture.

3. Diamonds

3.1. Constellations
The advantage to enter the adventure of diamonds is twofold: ultra-paradox and trans-operative, at once.

Diamonds are paradox and pataphysical.

The disadvantage of the calculus of indication is its low paradoxality and its hermetic narrowness towards operativity.

The relationship between difference-theory and the calculus of indication, Laws of Form, is parasitic. Difference theory is not contributing anything to the development of the calculus. It is solely interpreting some simple situations and transferring some terms into its jargon and Zettelkasten. There is no direct modeling between difference theory and indicational calculation.

The situation appears radically different in the case of diamond theory. Diamonds are per se defining the differential relation of system and environment immanently and intrinsically to their basic constructions (terms, notions, operations). Diamonds are build as an interplay of categories and saltatories.

Luhmann's difference theoretic relationship to the CI is interpretative. There is no operative counterpart in the CI which is directly and operatively supporting his difference theoretical interpretation. Historically, it was notorious, that the Bielefelder had been chasing prefaces to the Laws of Form. With an operative correspondence, this wouldn't have motivated so many chaser.

3.2. Diamond features
"The diamond modeling of the otherness of the others is incorporating the otherness into its own system. An external modeling of the others would have to put them into a different additional contexture. With that, the otherness would be secondary to the system/environment complexion under consideration. The diamond modeling is accepting the otherness of others as a "first class object", and as belonging genuinely to the complexion as such.

"Again, it seems, that the diamond modeling is a more radical departure from the usual modal logic and second-order cybernetic conceptualizations of interaction and reflection. The diamond is reflecting onto the same (our) and the different (others) of the reflectional system.

"In another setting, without the "antropomorphic" metaphors, we are distinguishing between the system, its internal and its external environment. The external environment corresponds the rejectional part, the internal to the acceptional part of the diamond. Applied to the diamond scheme of diamondized morphisms we are getting directly the diamond system scheme out of the diamond-object model. Thus, a diamond system is defined from its very beginning as being constituted by an internal and an external environment." (Kaehr, Diamond 2007)

CI
The repetition of a distinction, \[\[\] = \\], is a composition, hence, like all composition, the CI composition has to fulfil some matching conditions. They are well hidden, because there is not much content involved in the CI composition. But as I have shown in a slightly cabaret performance, there are matching conditions to be accepted.

\[\[\]:
Draw a distinction, mark it! Fine. Now, the same again! Draw a distinction, mark it!
But _where_ should I draw and mark it? Behind the blackboard, at the scribble board of the toilet? _When_ should I mark it? _How_ should I mark it, with a different color upon the first mark? And so on!

Obviously, it is supposed that I mark the mark bravely, one after the other on a strict line of a writing scheme. Therefore, the matching conditions are internalized in the mind of the distinction drawer and not yet inscribed at the blackboard (B. Brecht).

When I played this game with Luhmann 1993 at a research seminar in Hamburg, I didn't have the simple technical term of "matching conditions" at hand. But the message was clear and I got the feeling that the figure was well received.

But then, what's next? Waiting for a new preface from George?

**Interplay of categories and saltatories**

For diamond theory, the identity of objects of a category is defined by the hetero-morphisms of a saltatory. And complementary, the morphisms of a saltatory are defined by the objects of a category. Hence both distinctions, objects and morphisms, as basic starting concepts of category theory, have to be introduced at once. Both have, for their introduction, to be considered as being in a heterarchic order. This can be done without circularity only if there is conceptual space for the distribution of the concepts "object" and "morphism" accessible.

For diamond theory, the second-order concept of self-referentiality is deconstructed to the interplay of categories and saltatories in diamonds. Such an interplay isn't involved with relations and relational logic.

The system-paradox of "A system is a system and its environment" is transposed to "A diamond is an interplay of categories and saltatories. And saltatories and categories are a diamond of an interplay of categories and saltatories."

A system (diamond) is a system (category/saltatory) and an environment (saltatory/category) of a system.

**3.3. What's the sacrifice**

Diamonds are doubled, split and antidromic from the very beginning, which in itself is doubled and therefore neither a beginning nor an origin.

As a consequence, the hegemony of singular identity has to be given up. Such an identities is derivational. Singularity of identity, its uniqueness, hence, is a gravitational obstacle for flexible, metamorphic and heterarchic thinking and acting.

"First it distinguishes two sides and then it indicates one of these sides as the system (or the observer). As these operations are consecutive they constitute or 'consume' time. All observations are thus temporal: one cannot be on both sides of a distinction at the same time."

Such a necessity for consecutivity appears as a relict of old-European tradition, i.e. Western culture. This obsolete hegemony is the source of the Western concept of time.

As a consequence, the hegemony of singular identity has to be given up. Such an identities is derivational. Singularity of identity, its uniqueness, hence, is a gravitational obstacle for flexible, metamorphic and heterarchic thinking and acting.

A in a diamond world, there is no need for such consecutivity, and therefore for an understanding of time based on it.

This achievement of Western culture, its hegemony and its blind spot, has to be sacrificed. It anyway always was an illusion/allusion.

Because the operations are consecutive in time, because "one cannot be on both sides of a distinction at the same time", time is based on the identity of observations and distinction is based on the temporality of observation. Time is timing itself.

If such circularity is accepted, why not to accept simultaneity? Neither circularity nor simultaneity has a privileged relationship with absurdity.

Take a risk! Draw a distinction!

The risk concept of the theory of social systems is not only risky but adventurous, and, as it becomes more obvious, deemed to cause catastrophes.

**4. Beyond economy**

Time production as a result of a singularity of observation, which needs and produces, produces and
consumes, time and memory. For diamonds, no such implications have to be observed.

Hence, diamonds are more observer independent, are getting more radically rid of anthropological, egological and subjectivistic inheritences of old-Europaen philosophy. Hence, diamonds are deliberating difference-analytical limitations for system-thinking and are more open for a general theory of (social) systems.

There is no time for time production and consumption.

It, therefore, can be stipulated, that the time-structure of diamonds with its interplay of dromic and antidromic horizons, is independent of the economy of production and consumption.

"The idea of in-sourcing the matching conditions into the definition of diamonds seems to be in correspondence with the two main postulates of Chinese Ontology, i.e., the permanent change of things and the finiteness or closeness of situations. That is, diamonds should be designed as structural explications of the happenstance of compositions and not as a succession of events (morphisms). More exactly, diamonds are contemplating the interplay of exceptional and rejectional thematizations. Thus, morphisms with their matching conditions and composability are in fact of secondary order for the understanding of diamonds."

5. Graphematics: From difference to différance

If a sign is defined, introduced and characterised by differences and by relations, i.e. differentially and not relationally, and difference/différance is staged on an ontology-free arena as an interplay between categorical and saltatorical gestures, then diamonds are designing and inventing not semiotic but graphematic horizons (systems).

Semiotic systems appear in such situations as frozen diamonds.

6. Diskussion of the traditional view

6.1. Comments

There is, despite the massive multitude, a kind of an established view on sign theory, semiotics or sémiology, especially in its meta-theoretic formulations, conceptualizations and jargon.

First, a sign is a relational object: dyadic for Saussure, triadic for Peirce, tetradic for some other semioticians. As a consequence, signs are constituting a system of signs. Hence, signs tend to be characterized as systems and not as (relational) objects.

Second, despite all the onto-logical topics and inherited problems, signs are self-referential, they are able to refer to themselves by definition.

Third, there are many other characteristics for signs, like sign classes, sign relations, sign thematics, etc.

Fourth, signs are iterable. Independent of spécifique forms of identity and linearity of whatever media, the iterability of signs is the main characteristics of semiosis.

Endless

"Thus there is a virtual endless series of signs when a sign is understood; and a sign never understood can hardly be said to be a sign.”

6 - v. 1902 - MS 599 -Reason’s rules.

http://www.cspeirce.com/menu/library/rsources/76defs/76defs.htm

6.1.1. Relationality

Charles Sanders Peirce

One is: Peirce' semiotics is tradic-trichotomic and relational, hence based on triadic relations.

What is a sign? A sign is a triadic relation. As every student of math knows: Each n-adic relation might be represented by a succession of dyadic relations. Hence, n-adicity is reducible to dyadicity.

Well done! What is a relation? A relation is a subset of a set, i.e. a product set, a Cartesian set. Therefore, a sign is a subset of a set.
But what we are not told is that a relation is understood as a set and a relation as a set is a representation of a set. Hence, there are no genuine relations, because all relations are sets. Furthermore, a sign is a representation. And a relation is a representation of a set, hence a sign is a relation of a relation. A sign is not simply a relation, triadic or else, but a second-order relation, i.e. a relation of a relation over a set. And therefore a set of a set.

More technically, after the Kuratowski-Wiener intervention, a relation is an ordered set. And an ordered set is based on the pair axiom, which is guaranteeing ordered pairs, necessary for the definition of relations as sets of ordered pairs, which are themselves sets. But the idea of order, i.e. an ordered set, is a relational idea, based on a relational intuition, and is not presupposing the notion of sets.

**Sign**

"My definition of a representamen is as follow:

A REPRESENTAMEN is a subject of a triadic relation TO a second, called its OBJECT, FOR a third, called its INTERPRETANT, this triadic relation being such that the REPRESENTAMEN determines its interpretant to stand in the same triadic relation to the same object for some interpretant."

http://www.cspeirce.com/menu/library/rssources/76defs/76defs.htm

**Thirdness**

"[...]

In its genuine form, thirdness is the triadic relation existing between a sign, its object, and the interpreting thought, itself a sign, considered as constituting the mode of being of a sign. A sign mediates between the interpreting sign and its object. Taking sign in its broadest sense, its interpretant is not necessarily a sign. [...]

A sign therefore is an object which is in relation to its object on the one hand and to an interpretant on the other, in such a way as to bring the interpretant into a relation to the object, corresponding to its own relation to the object. I might say similar to its own for a correspondence consist in a similarity; but perhaps correspondence is narrower."

http://www.cspeirce.com/menu/library/rssources/76defs/76defs.htm

**Triadomany**

"I fully admit that there is a not uncommon craze for trichotomies. I do not know but the psychiatrists have provided a name for it. If not, they should. "Trichimania," unfortunately, happens to be preempted for a totally different passion; but it might be called triadomany. I am not so afflicted; but I find myself obliged, for truth's sake, to make such a large number of trichotomies that I could not [but] wonder if my readers, especially those of them who are in the way of knowing how common the malady is, should suspect, or even opine, that I am a victim of it."

(On trichotomies', CP 1.568, 1910)

**Ferdinand de Saussure**

The other approach is: Semiology in the sense of Saussure is dichotomic and relational, hence based on binary relations, which are building together a system.

A sign is the basic unit of language (a given language at a given time). Every language is a complete system of signs. Parole (the speech of an individual) is an external manifestation of language."

"In language there are only differences, and no positive terms

"L'idée fondamentale de Saussure est que le langage est un système clos de signes. Tout signe est défini par rapport aux autres, par pure différence (négativement), et non par ses caractéristiques propres ("positives") : c'est pourquoi Saussure parle de "système". (WiKi, fr)

A relation, especially a dyadic or binary relation, is a relation between entities, i.e. between positive terms. Again, a relation is a set and a set consists of elements which are positive terms.

What's about Saussure's kenome (Kénôme)?

Why should a difference be a relation? And why should a difference be dyadic?

There are a lot of dyads and dichotomies in Saussure's semiology.

http://www.revuedtexte.net/Saussure/Saussure.html

6.1.2. Self-reference of signs

"Such an object (or referent) of the sign can be a sign itself, and in this sense, self-reference becomes possible as a mode of a sign referring to a sign." (Peirce)

If a sign is defined as a triad of (object, representant, representamen), i.e. as a triadic relation, then there is no
definition given and no operator introduced, which would define such a self-application of a sign as referring to a sign, hence to itself. What is missing is a definition of an operation which is ruling the composition of signs.

Semiotics thus is not simply about signs but about the composition of signs. Bense, and later Toth, introduced 3 modes of primary compositions for signs: the iterative, the adjunctive and the superervative. None of them are well defined, especially the matching conditions for the composition of signs is left in the dark.

6.1.3. System theory of signs

Signs are not appearing as entities but as elements of a system. To understand signs, which themselves need to be understood to be signs, a theory of systems is required.

"Every language is a complete system of signs." (Saussure)

Hence, to understand signs we have to understand systems. And without surprise, to understand systems we have to understand signs. And as there are hundreds of definitions for systems there are even more definitions for signs. And vice versa.

Niklas Luhmann: 'Sign as Form'
A Comment
By Nina Ort and Markus Peter

Abstract: 'Sign as Form' is Niklas Luhmann's attempt to combine systems theory with sign theory by trying to integrate George Spencer-Brown's 'Laws of Form'. Systems theory operates with two sorts of metaphors representing either the meaning of inside and outside of a form (asymmetry) or both sides of an complementary couple (symmetry) which determine the subsequent arguments. The integration of an included third term, that would complete a semiotic sign, cannot be achieved by operating with dyadic distinctions however. This contribution discovers difficulties that arise from that combination and tries to show how the use of n-valued logic helps to overcome these problems."

http://www.imprint.co.uk/C&HK/vol6/v6_3-ort.html

"Even though self-reference is the topic of the present study, its basic assumption is neither a naïve theory of reference nor the structuralist or constructivist theory of the signs that have no referents. Our study will be based on Charles S. Peirce's semiotics, in the framework of which reference is the relationship of the sign to its object. However, the object to which a sign refers back is not a piece of the so-called real world, but something which precedes and thus determines the sign in the process of semiosis as a previous experience or cognition of the world. Such an object (or referent) of the sign can be a sign itself, and in this sense, self-reference becomes possible as a mode of a sign referring to a sign."

Winfried Nöth, Self-Reference in the Media
http://www.uni-kassel.de/iag-kulturforschung/projektbeschreibung.pdf

"Luhmann's systems theory is based on Spencer-Brown's dualistic philosophy of differences. This seems to make it incompatible with American pragmatic semiotician C. S. Peirce's triadic semiotics that seems to offer that trans-disciplinary theory of meaning and signification that the cybernetic functionalistic informational approaches are missing. But in his seminal work A calculus of [for, rk.] self-reference, Varela sees that the necessity of a third element in autopoiesis theory and second-order cybernetics has been overlooked and adds that to the system in a 'way that makes it compatible with Peirce's semiotics and still keeps the connection to cybernetics and autopoiesis.'"

Søren Brier, CBS, Cybersemiotics
Abstract

How to read polycontextural sign matrices? Are there such constructs like *polycontextural signs*? It is argued that there are in fact no entities or processes in the “real-world” like signs in the sense of semiotics at all. Semiotic signs are logocentric constructs realized by semioticians and defined by identity principles. This might be appropriate for a mono-contextural world-view but it is not sufficient for the experiences in a polycontextural world. An example is given, how to construct and read a polycontextural configuration as a texteme. Also composition/decomposition of sign classes are presented.

1. Do polycontextural signs exist?

1.1. Toth’s question

The semiotician Alfred Toth is asking: “Are there polycontextural signs?” (Toth, p. 1, 26.04.2009)

Is the lack of identity a sign for polycontexturality (of signs)?

"However, representatives of polycontextural theory have often pointed out that semiotics is clearly a monocontextural system in which the logical Law of Identity (and the other 2-3 fundamental laws of classical thinking) are valid without restrictions." (ibd., p.1)

Distributed over some polycontextural notions, Toth shows "that the classical semiotics has no identity and thus is polycontextural". Even if we could agree with this demonstration, the question remains: Is it enough for a semiotic system to be non-identical to be polycontextual?

Obviously, the first obstacle in the process to be declared as polycontextual on the base of a lack of identity is the concept of *negation* involved in the “non” of non-identical. Negation is too much in complicity with the system it is negating.

Toth gives his analysis an interesting turn in inverting the starting question "Are there polycontextural signs?"

"So, from here, the question should not be if there are polycontextural signs, but if there are monocontextural signs. *In classical semiotics, polycontexturality is hidden in the triadic-trichotomic structure of a seeming monocontexturality.*" (ibd., p.2)  

1.2. Polysemy as polycontexturality

Instead of denying identity, a complementary gesture might manage to introduce a
multitude of identities as a refutation of the dominance and hegemony of the logical and semiotic principle of identity.

Independent of the complexity of the semiotic matrix, the sign classes and their sign relations are always separated by their identity. Traditionally there are 10 sign classes recognized. All of them are properly distinguished from each other.

A dicent is a dicent and not a rhema or a symbol or a legi-sign, etc.

In an iterative sense, some complications might be produced for the 10 sign classes. Following Bense, we get, e.g., an argumentative-symbolic legi-sign as the semiotic modeling of formal languages (Kalkülsprachen), or a dicentic-symbolic sin-sign for “epic languages” and a dicentic-indexical legi-sign for “programming languages”.

To all those isolated sign classes and sign relations, semioticians are delivering more or less convincing linguistic, media-related or physical examples. Such identity constructs are reasonable for traffic systems and other unambiguous sign-related situations.

The intention to focus on identity of definitions and examples is not necessarily a semiotic action but an action, i.e. modeling, guided and ruled by the interests of identity, i.e. of identical identification.

With identity and identification, a specific form of rationality is supposed. Similar restrictions are introduced by Chomsky’s grammar. There is a strict distinction between meaningful and meaningless sentences. Nevertheless, all meaningless sentences are easily domesticated in a game which is opening up meaning for all.

My thesis therefore is: To all examples and to all distinctions there are always overlapping other distinctions involved that are suppressed, denied and rejected by such an act of identification.

As an example, the concept of “natural number” might be mentioned. Even for such an elementary concept like the “natural numbers” there is no identitive definition available. Most definitions (introductions, postulations) are circular or lost in the abyss of non-foundedness.

Hence, identification in the mode of identity is an ontological and epistemological procedure and follows not semiotic or sign theoretical necessity. Again, semiotics in a general sense, thematized as an identity system, is ruled by non-semiotic decisions.

In other words, semiotics as an identity system of whatever complexity is dominated by logocentric preconditions, in fact by linguistic and logical notions.

Therefore, semiotic distinctions in a polycontextural paradigm are not governed by the ontological is-abstraction but are involved into the free interplay of actional as-abstractions.

From a polycontextural point of view, signs are results of actions and actions are not necessarily reducible to single agents but might be realized as interactions between a multitude of mediated actor-systems. Each semiotic action is simultaneously involved and coupled with its environment, which contains itself a multitude of agents.

It turns out that classical semiotic systems are not actional but structural or relational and are based on a singular epistemic instance, i.e. interpretant.

1.3. Semiotic Matrix
A closer analysis of sign processes makes it obvious that signs are always intrinsically interwoven and overlapped with other signs. Signs as representamens are representing entities of a given world; polycontexturality is opening up worlds. Thus, signs in polycontextural situations are not simply representational but evocational. Such evocativeness of signs is not yet well studied. It is also not grasped by Bense’s creativity function of signs.

But this connectedness of signs in polycontextural situations is not the classical statement of the system-dependency of signs, i.e. the statement that signs are not occurring in isolation but necessarily in or as a system.

Semiotics in the sense of Bense and Toth is build on the base of the so called semiotic matrix, i.e. the Cartesian product of the sign components.

Then, sign classes are interpreted as parts of the matrix. These parts are disjunct and well separable from each other. There is no overlapping or penetration from and by other sign classes, i.e. classical semiotics is based on disjunctively separable sign classes.

As a reasonable result, such a kind of semiotics is not dealing with the whole matrix but only with its parts, i.e. the sign classes.

Transclassical semiotics, in the sense of polycontextural semiotics, is not in such a comfortable situation. Polycontexturality is not understood simply as a multitude of semiotic contextures but by its interactivity, reflectionality and interventionality between a plurality of contextures.

It is no surprise that, e.g. in polycontextural logic, the overwhelming majority of logical functions are not uniformly separable into cleanly defined sub-systems but are highly interwoven. That is, junctions, like disjunctions, conjunctions and implications, are a minority compared to the bulk of transjunctional logical functions.

It has to be stipulated therefore, that the same situation holds for a polycontexturally conceived semiotics.

From a strict terminological point of view it might be obsolete and confusing to still call this construction semiotics. A more appropriate title would be a mediation-system for interacting semiotics.

Hence a reading of a polycontextural semiotic matrix with the aim to collect sign classes doesn’t work anymore as a separation of mono-contextural sign constellations, like (3.1 2.1 1.1).

Such a reading of a polycontextural constellation obviously is producing “wild” beasts, “verwilderte Matrizen” (Toth), of, probably, not much use.

Polycontextural semiotics is forced to accept the semiotic tissue as a whole, i.e. as a game of interplaying contextures and their semiotic operations.

Hence, polycontextural semiotics is not reducible to separable sign classes. It always has to deal, at least for triadic semiotics, with the whole matrix. For more complex semiotics, a new kind of separability has to be studied, i.e. the separability of the general matrix into its overlapping sub-matrices.

Toth’s question “Are there polycontextual signs?”, thus has, at first, to be denied. By definition and tradition, signs are not polycontextural. (And there is obviously no such a thing like a “keno-sign”, too.)
1.4. Toth’s interpretation

In contrast to the just mentioned ‘holistic’, i.e. poly-contextural interpretation of arbitrary semiotic matrices as interplaying sub-matrices, Thot is giving an interpretation of polycontextural matrices by the means of classical strategies. Even a pentadic matrix gets its separated sign classes, i.e. 5-Zkl = (a.b c.d e.f g.h i.j) with a, ..., j ∈ {1, ..., 5}, this time not triadic but pentadic. But, as Toth is observing correctly, highly wild situations are disturbing such isolative interpretations.

Arbitrarity

"3. Kaehrs komponierte pentadische Matrix suggeriert grösstmögliche Arbitrarität bei der Kompositionen n-adischer und m-adischer zu (n+m-1)-adischer Matrizen und umgekehrt zur Dekomposition (n+m)-adischer Matrizen in (n-1-m)-adische Matrizen. Die einzige Anforderung an die “Richtigkeit” der komponierten Matrix wäre dann, dass die zueinander inversen Subzeichen die gleichen kontexturellen Indizes bekommen (z.B. (2.3) und (3.2), (1.5) und (5.1), etc.). In letzter Instanz führt diese Arbitrarität also dazu, dass in Übereinstimmung mit einer obigen Festellung die abstrakte Form einer pentadischen Zeichenklasse als

5-Zkl = (a.b c.d e.f g.h i.j)
mit a, ..., j ∈ {1, ..., 5}
anzusetzen ist. Da ferner die triadischen Hauptwerte a, c, e, g, i nicht mehr paarweise verschieden sein müssen, kann jede x-beliebige Folge von 6 Ziffern natürlicher Zahlen als pentadische Zeichenklasse interpretiert werden.” (Toth, Interakt Sem1Sem2, p. 3, 2009)

This arbitrarity might lead to a wild and nonsensical use of the concept of sign classes. Toth gives a possible solution for a reduction of the “wilderness” of the pentadic situation for “Haupt-Zeichenklassen” and “Neben-Zkln”.

“Haupt-Zeichenklassen”

"4. Eine Einschränkung für diese völlig verwilderte Menge von Zeichenklassen könnte man daraus entnehmen, dass man wie bei der triadischen Matrix die Reihen der pentadischen Matrix als “Haupt-Zeichenklassen” interpretiert und aus den pentatomischen Pentaden der dyadischen Subzeichen Regeln zur Komposition von Zeichenklassen ableitet.” (ibd., p.3)

“Neben-Zkln”.

2.1 5-Zkl = (5.a 4.b 3.c 3.d 1.e):
(a = 1) --> b = 1, c = 5, d = 4, e = 1
(a = 2) --> b = c = d= 2, e = 4
(a = 5) --> b = c = d = e = 5
2.2. (5-Zkl = (3.a 3.b 3.c 2.d 3.e)) --> a = e = 5, b = 4, c = d = 3

Die Reihen der Matrizen enthalten triadische Sprünge und Wiederholungen [...]" (ibd., p. 3/4)

Thus, a sign class with “strange-values” is producing some kind of jumps and gaps in the arithmetics of semiotics. Toth mentions the examples:

(1-3-3-4-5) of the column (1),
(3-2-3-4-4) of the column (2) and
(3-2-3-3-3) of the column (3) of the matrix below.
The columns (4) and (5) are not disturbed by "stange-values". The same happens to the rows of the matrix.
However whatever kind of restrictions are introduced for a reasonable handling of complex sign classes, with \( m \geq 3 \), the strategy of selecting a single isolated chain of "prime signs" out of the matrix remains the same.

Without doubt, there might be some interesting insights possible with this approach, but there will still be an overwhelming majority of situations excluded, i.e. not interpreted as reasonable semiotic constellations. With that, a new, meta-semiotic problem occurs: What are the criteria of exclusion of the non-semiotically interpreted constellations? In other words, a criterion to distinguish between acceptable and non-acceptable constellations has to be introduced.

Again, as most junctional “value-sequences” in polycontextural logic are disturbed by external values, Gunther's "Fremdwerte", which are getting a logical meaning only in the context of an interplay between different mediated logical systems, the “Fremdwerte” of semiotic sign classes incur the same destiny: they are members of other sign classes interacting together in the complex semiotic game.

Therefore, polycontextural semiotics has to study, at least, both directions of the interplay: the interactional (reflectional, interventional) aspect between contextures, i.e. the transcontextural interplay, and the intra-contextural aspect of the disturbance by transcontextural interpenetrations.

2. From signs to textemes

Instead of excluding “strange” sign classes or to stretch adventures interpretations about gaps and jumps in the chain of prime signs, their origin in the complexity of polycontextural semiotics has to be considered first.

Because such situations are fundamentally different from semiotic approaches, the idea of textemes had been introduced. From the position of the idea of textemes, signs in a semiotic sense, are reductions of textemes.

Therefore, a first step to a general theory of interactional semiotics on the base of the new concept of textemes, i.e. bi-sign systems or anchored diamonds, consisting of the semiotic intra-kernel and the semiotic internal/external environments, and its interplay, is proposed.

A texteme consists of two diamondized anchored signs, i.e. bi-signs, inter-playing together by their mediated external environments. Hence, a texteme is an interplay of two bi-signs. A bi-sign is a diamondized anchored sign, i.e. a sign with intrinsic environments and its anchor.

This is a kind of bottom up introduction. Because we know signs and have not yet experienced textemes, this way of building up textemes is legitimate. But nevertheless, it works only because we know how to construct textemes out of signs which are not able to offer any of the principles of textemes, that are needed to realize such a construction, like their chiastic interplay between the environments of signs and the anchoring of signs.
As we know well enough, signs lack environments, there is no chance to construct out of signs in a sign-theoretical sense a semiotic environment of the sign concept. And obviously, there is no such mechanism as a chiasm in the sense of proemiality for signs. And again, semiotics is not offering any insight and mechanism for anchoring signs. Hence, neither environments, internal and external, nor interactions between signs based on their environments and their anchoring are conceivable.

These statements are surely in conflict with the well established interactional socio-, bio-, zoo-semiotic programs as well as with the advances in computational semiotics. From the point of view of polycontextural and diamond theoretical approaches to sign theory, those programs have to be seen as applications of classical, a priori non-interactional semiotics, onto semiotics, and not as anything else. Their merits are to be communicable in a society of traditionally trained knowledge-mongers.

Hence, a decomposition chain might clarify the concept of texteme:
A texteme is decomposable to its interacting bi-signs by excluding its chiasitic interactivity.
A semiotic diamond is a bi-sign, de-rooted from its anchor.
A single bi-sign is disconnected from its neighbor bi-sign, hence it is a bi-sign without interaction but realizing an anchored semiotic diamond with its isolated, and hence restricted, environment.
A sign is a semiotic diamond, depraved from its environment and its anchor.

This decomposition from the texteme to the sign has no reverse: There is no semiotic mechanism per se to construct out of semiotics the concept of textemes.

The complexity of a basic texteme is 12, i.e. 2x3 for its "signs", 2x2 for its anchors, and 2x1 for its environments.

It might be asked if such matrices exists as semiotic matrices and not merely as mathematical matrices. A possible answer might be given with a semiotic interpretation of the texteme construction.

Sign\(_2\) of bi-sign\(_1\) shall be interpreted by the semiotic matrix \(\text{Sem}(3, 2)\) and \(\text{Sem}(3, 2)\) shall correspond to the sign\(_2\) of bi-sign\(_2\). Such 3x3-matrices are well accepted as semiotic matrices. Therefore, the step to compose such matrices to a 5x5-matrix shouldn’t cause to many problems. Semiotic matrices are occurring as numeric matrices and as matrices over M, I, O.

The idea of non-identical but polycontextural and multi-layered semiotic constellations seems to be accessible for formal treating within such a construction of interplaying semiotics. Hence, such inconsistent situations, where a dicit appears at once as a rhema, including all other kinds of overlapping and metamorphosis, are getting a formal framework for their interplay.

With that in mind, the semiotic interpretation of the texteme below follows naturally.
It is an example, how to interpret matrixes for polycontexturally conceived sign-complexions, i.e. textemes.

**Procedure**
The (OMI)-matrix SCI\(3,2\) is translated into the corresponding numeric matrix MM \(3,2\), with its 2–subsystem indices. For both, a matrix-composition with environments and anchors are presented. The result of this composition, with the matching conditions (overlapping) 3.3\(_1\) \(\equiv\) 3.3\(_2\), is written as Texteme\((5,3,2)\). The environments of Sem\(_1\) and Sem\(_2\) are reduced to \(\overline{3.3_1} \leftrightarrow \overline{3.3_2}\) corresponding to the overlapping conditions, and omitting the micro-environments of the 2-sub-systems of the triadic matrices.

![3-contextual semiotic matrix](image)

Matrix notation for \([1, 2] – anchored texteme\):

\[
\Pi^{(3,2,2)}_{\text{Type texteme}} \begin{pmatrix}
M & \square \\
\downarrow & \nearrow \\
I & \circ \rightarrow 1
\end{pmatrix}
\]

\[
\begin{pmatrix}
O.O_{1,3} & O.M_{1} & O.J_{3} \\
M.O_{1} & M.M_{1_2} & M.J_{2} \\
I.O_{2} & I.M_{2} & I.J_{23}
\end{pmatrix}
\]

\([1, 2]\)

Matrix notation for \([1, 2] – anchored texteme, without 2 – subsystems\):

\[
\Pi^{(3,2,2)}_{\text{Type texteme}} \begin{pmatrix}
M & \square \\
\downarrow & \nearrow \\
I & \circ \rightarrow 1
\end{pmatrix}
\]

\[
\begin{pmatrix}
1.1 & 1.2 & 1.3 \\
2.1 & 2.2 & 2.3 \\
3.1 & 3.2 & 3.3
\end{pmatrix}
\]

\([1, 2]\)
More precisely, the matching conditions for the composition of overlapping matrices are not the matching conditions of concatenational composition of morphisms but overlapping conditions of different complexity, in this case of length 1. Hence, concatenational matching conditions for morphisms are overlapping in zero elements, while the proposed composition of matrices is overlapping in one element, here 3.3\[1 = 3.3\[2\].

Again, 3.3\[1 is not the codomain of Sem\[1 and 3.3\[2 is not the domain of Sem\[2 of the composition Sem\[1 o Sem\[2. Thus, it is just an abbreviation to call those “matching
conditions”, MC, simply matching conditions and not overlapping matching conditions.

Such overlapping conditions had been called “mediation conditions”, MC, in the “Matrix-paper”.

From a logical perspective, overlapping is producing contradictions. Therefore, a proper treatment of overlapping patterns has to consider its morphogrammatic foundation.

### 2.1. Again then, what is a polycontextural sign?

The term “polycontextural sign” is an abbreviation for the wording: “Signs in polycontextural constellations”. This means that signs and sign systems are conceived as distributed and mediated, i.e. disseminated over the kenomic matrix.

In the same sense, as there is no poly-Lambda Calculus, but lambda calculi disseminated over the kenomic matrix, and the label “poly-Lambda Calculus” is a simple, maybe misleading, abbreviation, polycontextural semiotics or poly-semiotics, are abbreviations for the dissemination of semiotics.

This is a conservative interpretation because it is conserving the original concept of signs, i.e. its triadic-trichotomic structure, and is not changing or deconstructing it towards another conception. But the experiences with conservative expansions are enabling new decisions which are deliberating from the acceptance of the basic system and its restrictions.

From the point of view of polycontextural dissemination, even classical semiotics appear as polycontextural, simply because it is distributed too, albeit only over a single place and not able to be aware of it. What's called its blind spot.

**More exercises**

For the classical matrix MM\(^{(3, 3)}\) the disjunctivity of the sign classes holds.

\[
\text{MM}^{(3, 3)} = \begin{bmatrix}
O.O_1 & O.M_1 & O.I_1 \\
M.O_1 & M.M_1 & M.I_1 \\
I.O_1 & I.M_1 & I.I_1
\end{bmatrix}
\]

\[
\text{MM}^{(5, 3, 2)} = \begin{bmatrix}
O.O_1 & O.M_1 & O.M_1 & 1.4 & 1.5 \\
M.O_1 & M.M_1 & M.I_1 & 2.4 & 2.5 \\
I.O_1 & I.M_1 & I.I_1 & 4.1 & 4.2 \\
4.1 & 4.2 & M.O_2 & M.M_2 & M.I_2 \\
5.1 & 5.2 & I.O_2 & I.M_2 & I.I_2
\end{bmatrix}
\]

Only the two matrices MM\(_1\) and MM\(_2\) are considered, the rest is omitted.

**Symmetrical case of interaction**:

\[
\text{interact}_{\text{sym}} = \text{MM}^{(5, 3, 2)} = \begin{bmatrix}
O.O_1 & O.M_1 & 4.1 & 1.5 \\
M.O_1 & M.M_1 & 2.4 & 2.5 \\
I.O_1 & I.M_1 & I.I_1 & 4.1 & 4.2 \\
4.1 & 4.2 & M.O_2 & M.M_2 & M.I_2 \\
5.1 & 5.2 & I.O_2 & I.M_2 & I.I_2
\end{bmatrix}
\]

\[
\text{[bit]} \quad \text{O}_1 \quad \text{O}_2 \\
\text{M}_1 \quad \text{sem}_1 \quad x \\
\text{M}_2 \quad \text{trans}_2 \quad \text{sem}_2
\]
Asymmetrical case for interaction \((\text{O.M}_2 / \text{M.O}_2) \rightarrow (\text{O.M}_1 / \text{M.O}_1)\):

\[
\begin{bmatrix}
\text{O.O}_1 & \text{O.M}_2 & \text{O.I}_2 \\
\text{O.M}_2 & \text{M.M}_1 & \text{M.I}_1 \\
\text{O.I}_2 & \text{I.M}_1 & \text{I.I}_1 = \text{O.O}_2 & \text{O.M}_2 & \text{O.I}_2 \\
4.1 & 4.2 & \text{M.O}_2 & \text{M.M}_2 & \text{M.I}_2 \\
5.1 & 5.2 & \text{I.O}_2 & \text{I.M}_2 & \text{I.I}_2
\end{bmatrix}
\]

All sign classes composed out of the matrix \(\text{MM}^{(5, 3, 2)}\) are homogeneous, i.e. clean of “strange values”, i.e. \(\text{id(\text{MM}^{(5, 3, 2)}) = \text{MM}^{(5, 3, 2)}}\).

All combination of the original matrix \(\text{MM}^{(5, 3, 2)}\) are produced by operations on the matrix. A set of important operators had been introduced as the super-operators, \(\text{sop} = \{\text{id, perm, iter, repl, red, bif}\}\). The above interactions are based on the interactional operation “bif”.

Because there is no space offered by the notation of the matrix \(\text{MM}^{(5, 3, 2)}\) for iterations and replications, the presentation is still a short for the full scheme, as it was introduced in previous papers.

The sign class \((\text{O.O}_1 \text{O.M}_2 \text{O.M}_1)\) with its contextual type \((1, 2, 1)\) is obviously disturbed by the “strange” value \(\text{O.M}\) of contexture \(2\), its meaning isn’t easy to determine as an isolated event. Studied as the result of an interaction between the two matrices, the meaning is well defined as a rejectional value from the position of the first matrix and as a penetrational value from the position of the second matrix.

**Composition and decomposition**

Polycontexturality is mainly about composition (mediation) and decomposition of systems.

Hence, a sign class like \(5-\text{Zkl} = (5.a\ 4.b\ 3.c\ 3.d\ 1.e)\) with a, ..., e \(\in\{1, \ldots, 5\}\) has to be studied in a double way: globally, as the whole pattern, i.e. \((5.a\ 4.b\ 3.c\ 3.d\ 1.e)\), and locally, as a composition of sub-systems, here classical semiotic systems or sign classes 3-Zkl.

Hence, the sign class 5-Zkl is understood as a composition of the sign class 3-Zkl, which is representing the Peircean semiotics distributed over 10 different places in the sign class 5-Zkl.

The advantage of the decomposition method is clear. Each sign class m-Zkl is decomposable into its sub-systems, the distributed sign class 3-Zkl.

There is no need to invent infinite many different semiotics for arbitrary m-Zkl.

On the other hand, the distribution method is not restricted to triadic-trichotomic semiotics. For each \(n<m\), there is a distribution of n-Zkl in m-Zkl.

**Morphograms for sign classes**

If we insist that 3-Zkl is defined as \(<3.x\ 2.y\ 1.z>\), then obviously, patterns like \(<3.x\ 4.y\ 5.z>\) or \(<1.x\ 4.y\ 5.z>\) are not defining Peircean sign classes at all.

The distribution of 3-Zkl over the places offered by m-Zkl is forcing an abstraction from the concrete value set \{1, 2, 3\}. What is distributed then is the pattern of the 3-Zkl and not the concrete singular 3-Zkl with the values 1, 2, 3. This pattern is called the morphogram of 3-Zkl.
With that, it is natural to introduce the remaining 4 morphograms for \( m=3 \) as reductions of the original sign class, thus: \( <3.x \ 2.y \ 2.z> \), \( <3.x \ 3.y \ 1.z> \), etc.

\[
morph(ZR^{(3,2)}) = \{ MG_1, MG_2, MG_3, MG_4, MG_5 \}
\]

The values of \( x, y, z \in \{1, 2, 3\} \) have not been considered.

This exercise was done with my paper “Interactional operators in diamond semiotics” and “Matrix” for the case of complexity 3 and 4. Hence, again for 4 and further results for 5.

\[
4-Zkl = ZR^{(4,2)}:
\]

\[
ZR^{(4,2)} = (4, a \ 3.b \ 2.c \ 1.d) \text{ with } a, ..., d \in \{1, ..., 4\}
\]

\[
Z_R^{(3,2)} = <3.x, 2.y, 1.z> \text{ with } x, y, z \in \{1, 2, 3\}
\]

\[
\text{decomp}(ZR^{(3,2)}) =
\[
\left( ZR_1^{(3,2)}, ZR_2^{(3,2)}, ZR_3^{(3,2)}, ZR_4^{(3,2)} \right)
\]

\[
= \begin{bmatrix}
3.x, 2.y, 1.z, --, --, --, --, 3.x, 2.y, 1.z
3.x, 2.y, --, --, 1.z
3.x, --, --, 2.y, 1.z
\end{bmatrix}
\]

**Matching conditions for \( ZR^{(4,2)} \)**

\[
(3.x)_1 \neq (3.x)_3 \neq (3.x)_4
\]

\[
(2.y)_1 \neq (3.x)_2 \neq (2.y)_3
\]

\[
(1.z)_1 \neq (2.y)_2 \neq (2.y)_4
\]

\[
(1.z)_2 \neq (1.z)_3 \neq (1.z)_4
\]
Generalizations
The method of composition/decomposition holds generally for n-adic constellations of sign classes too.
\( m\)-ZR\((m,n) = ZR^{(m,n)} = ZR^{(m,2)} = \{ 5, a, b, c, d, e \} \) with \( a, \ldots, e \in \{ 1, \ldots, 5 \} \)

\[ 5 - ZKL = ZR^{(5,2)}: \]
\[ 5 - ZKL = ZR^{(5,2)} = \{ 5, a, b, c, d, e \} \text{ with } a, \ldots, e \in \{ 1, \ldots, 5 \} \]

\[ ZR^{(3,2)} = < 3, x, 2, y, 1, z > \text{ with } x, y, z \in \{ 1, 2, 3 \} \]
\[ \text{decomp}(ZR^{(5,2)}): \]
\[ ZR^{(3,2)}_1 = < 3, x, 2, y, 1, z > \text{ with } x, y, z \in \{ 1, 2, 3 \} \]
\[ ZR^{(3,2)}_2 = < 3, x, 2, y, 1, z > : (3, 4, 5) \]
\[ ZR^{(3,2)}_3 = < 3, x, 2, y, 1, z > : (1, 2, 4) \]
\[ ZR^{(3,2)}_4 = < 3, x, 2, y, 1, z > : (1, 2, 5) \]
\[ ZR^{(3,2)}_5 = < 3, x, 2, y, 1, z > : (1, 3, 4) \]
\[ ZR^{(3,2)}_6 = < 3, x, 2, y, 1, z > : (1, 3, 5) \]
\[ ZR^{(3,2)}_7 = < 3, x, 2, y, 1, z > : (1, 4, 5) \]
\[ ZR^{(3,2)}_8 = < 3, x, 2, y, 1, z > : (2, 3, 4) \]
\[ ZR^{(3,2)}_9 = < 3, x, 2, y, 1, z > : (2, 3, 5) \]
\[ ZR^{(3,2)}_{10} = < 3, x, 2, y, 1, z > : (2, 4, 6) \]
